SODIUM CITRATE TRANSFUSIONS

A STUDY OF ONE HUNDRED CASES *

A. L. GARBAT, M.D. (NEW YORK)
Captain, M. C., U. S. Army; Chief of Laboratory, General Hospital No. 12
BILTMORE, N. C.

So much has been said for and against the transfu-n of *blood mixed with sodium citrate that it is* portant for every one who has had experience with his method to publish his results. I shall record 100 ransfusions on sixty-eight patients.

TECHNIC

It is not essential to review the literature referring o the various modifications of Lewisohn's original echnic. *In our series*, the blood was usually *collected* nto two large measuring beakers, each one holding 0 c.c. or more. The blood was then filtered through auze directly into an infusion flask or arsphenamin pparatus and allowed to run into the vein of the tient. Several technical points are of importance:

1. A large caliber cannula is used to get the blood from donor so that the required quantity of *blood* is obtained as short a time as possible.

2. A large cannula is also used for the recipient with the ame object in view. Naturally, there are limitations to this ate, depending on the particular illness or condition of the atient; for example, cardiac or pulmonary disturbances emand a slower current of blood, etc.

3. The blood should be kept at body temperature while it is *utside of the body and kept outside of the body* as short a ime as possible. *This can* be *assured* by *transferring* the lood *from* the *receptacles* in *which* it was collected into Erlenmeyer flasks or bottles, and these can be placed into a asin of warm water. Lewisohn has recently advised the use vacuum bottles.

4. Although it is absolutely essential to keep stirring the lood and citrate solution so as to mix them thoroughly and hus prevent coagulation, it is equally important not to stir oo vigorously in fear of the possible physical destruction f the various blood *constituents*.

5. *The sodium citrate must be chemically* pure and the vater in which it is dissolved freshly distilled.

SELECTION OF DONORS

The usual agglutination and hemolysis *tests* were lone as a *preliminary step to all transfusions. In no* nstance was *an* incompatible blood employed. The esults of the transfusions showed that blood tests *in* itro were an *absolute* index to the compatibility of the lood in vivo, as no symptoms of blood destruction, such as hemoglobinuria, were obtained. I believe *that* *there is no more doubt* as to *the* desirability of *blood* tests before transfusion. Naturally, in instances in which the proper donors cannot be procured or procured rapidly enough, the transfusion should not be omitted if its indications are extremely urgent as a life-saving measure. The risk of disturbances due to incompatibility may be taken, and under such circumstances it is wiser to select a donor whose serum agglutinates or hemolyzes the red blood cells of the patient rather than a donor whose red blood cells are acted on by the patient's serum.

In *performing* our agglutination and hemolysis tests, I employ the macroscopic *method, in which* 0.15 c.c. of serum (3 drops) from the patient is mixed in a small test tube with 0.05 c.c. (1 drop) of a 10 per cent. *red blood cell emulsion from* the donor and vice versa. The *mixtures* are incubated for three hours, placed *in the ice box* for twenty-four hours and then read. *If the result* is doubtful, the mixtures are examined *microscopically*. Whenever the condition of the patient warrants it, this method of selection of donors is advised for greater accuracy, rather than any of the more rapid or microscopic methods of agglutination with small quantities, even though it often carries with it the *disadvantage* of puncturing the vein in order to *obtain* sufficient blood. On the other hand, the advantage gained thereby is deemed of great importance; for, while one cannot say that all reactions after transfusion are due to *imperfect* matching of donor and patient, *some* reactions may certainly be explained in that way.

REACTION

A frequent objection raised to the sodium citrate method is that marked reactions are obtained after this mode of transfusion.

In our series of 100 transfusions:

(*a*) Forty-eight per cent. were associated with no reaction whatever; no abnormal manifestations either subjectively or objectively were noted.

(*b*) Ten per cent. had practically no reaction to speak of. There was a rise in temperature of 1 or 2 degrees for several hours, but the patients had no abnormal subjective sensations.

(*c*) Forty-two per cent. showed a definite reaction consisting of chilly sensations or chills, and fever; and in the severest types, vomiting. Of the 42 per cent.:

There was a rise of temperature up to 103 to 105 in eight.

There was a rise of temperature up to 102 to 103 in nineteen.

There was a rise of temperature up to 101 to 102 in fifteen.

Many of these temperatures remained elevated only *for a number* of hours and came down rapidly by a *form of crisis*; in the others, the fever came down by lysis, and three or four days were *required until the* normal point was reached.

---

*From the Wards and Laboratory of the Lenox Hill Hospital, New York.

Of the 42 per cent. also, five had reactions with quite severe chills; twenty-five had milder but distinct chills, and seven just had chilly sensations or a feeling of coldness but no definite chill.

The chill usually comes on about one half to three quarters of an hour after the transfusion. If the blood flows in too slowly, as warned against above, this chill may come on during the time that the transfusion is being given and naturally is very disagreeable. In the severest type of reaction the chill itself as both observed by myself and as described by a patient, who was an intelligent writer, is more severe in intensity than any other form of chill (malaria, sepsis, etc.). It begins usually in the lower extremities by a feeling of coldness gradually extending up the spine and then over the entire body. Associated with this general, constant coldness, there are at intervals varying from seconds to minutes, exacerbations of this cold feeling turning into an active chill, so that the patient shakes. These exacerbations in instances are extreme, so that the patient is often jolted violently up and down in bed. The lips become blue, the pulse becomes rapid and the skin becomes extremely hypersensitive so that if, for example, the observer touches the side of the patient's face in order to take the temporal pulse, this will be sufficient stimulation to bring on a renewed chill. The patient usually asks for more and more blankets; but *no matter how much warmth is applied, it is not sufficient to remove or prevent the occurrence of another chill.* These chills last from five minutes to a half hour, and their subsidence is evidenced by the chilly exacerbations first leaving, and then the feeling of coldness disappears also. In contrast to malaria, subsequent perspiration is absent or only slight.

It goes without saying that such a marked reaction as the one just pictured is exceptional. It is described here because I wish to emphasize that in spite of the apparent severity, no harmful results either to the physical condition of the patient or to the value of the transfusion could ever be directly attributed even to such a reaction. All intermediate grades of disturbances occur between this severe syndrome and the absence of chills or chilly sensations. Rise of temperature usually follows the chill and will persist for several hours; or, as was said above, normal temperature may not be reached for three or four days.

It is illogical, as is done by some, to advise another method of transfusion in a particular instance because that particular patient seems too weak to stand a possible severe reaction. I was recently requested to use unmixed blood in a case of sepsis because the man was very weak and the consultant wished to avoid a possible reaction. The Unger method was employed; 500 c.c. of blood were transfused in a very few moments; and the patient had a reaction as severe as, if not severer than, any that I had ever noted with the method of sodium citrate.

Undoubtedly, there is something about the cause of the reactions that we do not understand. At one time I thought that possibly the blood platelets were the cause of the reaction; in other words, that while compatibility of the red blood cells exists, the blood platelets may not be compatible. My experimental work, however, showed that in the human being all blood platelets belonged to the same group and that there were no iso-agglutinins or isohemolysins for blood platelets. While a serum might be rich in agglutinins or lysins for the red blood cells of another individual, the blood platelets of the latter were in no way affected by that serum.

I have made the observation that certain donors regularly give severe reactions and others none at all. While this statement should not be taken without reserve, it is mentioned for corroboration by other authorities. Even if it does prove to be so, it still does not explain the phenomenon.

To summarize the question of reactions, it can be stated that the percentage of reactions after the sodium citrate transfusions is undoubtedly higher and possibly the reactions are severer than with the other methods of transfusion. At no time, however, are they harmful in any way, and therefore they should not influence one to select another method; especially so, when one considers the great technical and manifold other advantages of the citrate method. The advantage of its great simplicity is, to a certain degree, even a slight disadvantage. It is employed by physicians who have little if any surgical experience so that the transfusion usually takes much longer than it should, and the blood is allowed to remain outside the body unnecessarily long; in this way the method may fall into disrepute rather than be one of our greatest helpmates in medical and surgical therapy.

ACCIDENTS

The one accident to be considered in sodium citrate mixtures of blood, aside from the accidents of transfusions in general, is the possibility of the blood's clotting. In earlier transfusions this occurred several times and was due to one or two causes. First, that the sodium citrate and blood were not thoroughly mixed, and secondly, that a 0.2 per cent. mixture of sodium citrate and blood, that is, 50 c.c. of a 2 per cent. solution of sodium citrate to 450 c.c. of blood, was not sufficient for some donors; especially for donors who had already been used for transfusions. Both of these *errors can be overcome, the first by stirring the blood* and sodium citrate constantly, thoroughly, but gently, and the second by employing a 0.25 per cent mixture, that is, 50 c.c. of a 2.5 or even 3 per cent. solution of sodium citrate to 450 c.c. of blood. To be even more certain that no minute clots slip through, the blood is filtered (through several layers of gauze) into the infusion apparatus.

INDICATIONS FOR WHICH TRANSFUSIONS ARE UNDERTAKEN

The next and most important question to decide is whether blood mixed with sodium citrate is as efficacious as whole or unmixed blood. In order to discuss this, it would be wise to classify the indications for which transfusions are undertaken. These are:

1. To replace blood in hemorrhage of all kinds:
    (*a*) During the act of bleeding (and at the same time also to help stop the bleeding).
    (*b*) After the bleeding has stopped and an anemia with its sequelae remain.
2. To stimulate the blood-forming organs in blood diseases:
    (*a*) Pernicious anemia.
    (*b*) Leukemia.
3. To alleviate or cure hemorrhagic conditions:
    (*a*) Hemophilia.
    (*b*) Hemorrhagic diseases of the new-born.
    (*c*) Purpuras.
    (*d*) Complicating secondary hemorrhagic diseases, as jaundice, grave anemia and infections.

4. To act as a stimulant or tonic:
   - (a) Before operations.
   - (b) In debilitated conditions.
   - (c) In acute shock.
5. To neutralize or overcome effects of poisons:
   - (a) Bacterial infections.
     - Bacteremia:
       - Endocarditis.
       - Infections with pyogenic bacteria; typhoid; etc.
     - Toxemia only:
       - Diphtheria.
       - Peritonitis, etc.
   - (b) Chemical:
     - Diabetic coma.
     - Acute gas poisoning.
     - Acute yellow atrophy of the liver, etc.

HEMORRHAGE

As for the first class of cases, twenty-eight transfusions were performed to replace blood, immediately or some time after an acute hemorrhage had taken place. These hemorrhages occurred from various causes, such as nasal, pulmonary, vesical and uterine hemorrhages, including postpartum hemorrhages and hemorrhages from myomas, bleedings after tonsillectomy, bleedings from gastric ulcer, gastric cancer, duodenal fistula, hemorrhoids, and bleeding during typhoid fever. There were three deaths in this entire group. One of these patients had very severe uterine hemorrhage associated with pregnancy and a very marked nephritis. One was a young man who was suffering as a result of a severe gastric hemorrhage which set in long after a gastro-enterostomy for ulcer. He ultimately died of inanition. The third was an old man with severe hemorrhage from papilloma of the bladder. He had a moderate nephritis and never recuperated from the shock of the operation.

In all the other transfusions the results were absolutely ideal. Improvement started almost immediately. In several instances the results were short of miraculous. Patients in marked collapse, almost exsanguinated from the loss of blood, would speedily recover and recover sufficiently well to withstand a severe operation, such as a panhysterectomy, with comparatively little shock. In such cases another transfusion was given immediately after the operation, or part of the original blood was kept for this purpose. Naturally with no other form of transfusion could this have been done. In all cases in which transfusions were given not only to replace the lost blood but also to help in stopping the bleeding, this end too was attained. In the cases of pulmonary hemorrhage, of gastric or duodenal ulcer, hemorrhage after tonsillectomy or nasal operation, the transfusions undoubtedly helped to check the hemorrhage. This was particularly so in those with repeated or prolonged bleeding. In spite of some hesitation about transfusing immediately after an active hemorrhage on account of the danger from the rise of the blood pressure, all the patients received from 800 to 900 c.c. of blood without any harmful effects whatsoever. It is wise, however, to keep this possible danger in mind. In general, I am inclined to favor transfusions of large amounts of blood, naturally taking into consideration the size of the patient, his physical condition and any other possible contraindications.

Thus, it is noted that the sodium citrate transfusion is perfectly effective for the class of cases in which hemorrhage or its results has to be dealt with. Especially for the acute hemorrhage occurring in such great numbers at present on the battlefields, this form of transfusion is the only one to be considered. It can be performed very readily in the field, where large quantities of blood from various groups can be held in readiness. Rapid transfusion tests can be performed, or if the condition of the patient is too serious, these may be omitted entirely and blood from a Group II donor given. It will undoubtedly save many a comrade.

PERNICIOUS ANEMIA

The introduction of direct transfusion as a curative measure in pernicious anemia encouraged the medical profession only for a comparatively short time. I know of no case of true pernicious anemia in which there has been permanent cure by transfusion alone, no matter what method was employed. Recently, our hopes for conquering this disease have again been stimulated by the introduction of splenectomy as a therapeutic measure. It can already be said that the removal of the spleen can be offered only as a possible means of cure, and not as a certain means. In the early cures there have been relapses, and while I do not wish to express undue pessimism, it must be said that splenectomy with or without transfusion, either before or after operation or both, has not yet solved the problem of pernicious anemia.

The term "pernicius anemia" must be confined to that very severe grade of primary progressive anemia so classically described by Addison, in which no apparent causation is evident. It should not apply to these cases of pseudo pernicious anemia simulating the primary progressive but actually secondary to some focal infection discovered sooner or later. On the other hand, it is possible that all cases of true primary progressive pernicious anemia are not primary, but secondary to some such focal infection in most instances not discovered; such assumption has still to be definitely proved. The most one can expect of transfusion in pernicious anemia is, first, to overcome the symptoms of the severe anemia, and, secondly, to institute a remission and in this way prolong the patient's life, possibly for many years. The question at present under investigation is whether blood mixed with sodium citrate can accomplish this as well as whole or unmixed blood.

In this report thirty-three transfusions were performed on fifteen patients. Five patients showed little or no effect; of these, three were practically moribund at the time of transfusion and died within a few hours or days. The other two showed improvement for several days, and then, in spite of the temporary increase in hemoglobin and red blood cells, the anemic symptoms rapidly reappeared and the patients died. It is certain that no other method of transfusion would have succeeded any better, for the tissue cells were not in a condition sufficiently alive to respond to the stimulus. Of the other ten patients, all showed a progressive improvement following one or more transfusions. While it is known that patients with pernicious anemia have remissions even without transfusion, it seemed that remissions were initiated more promptly with the aid of transfusions. These remissions lasted from four weeks to twelve months, and in one case two years. All the cases of this series were of a severe type of pernicious anemia and came under treatment late during the course of the disease. It is certain that had not transfusions been done, death would have occurred within a short period of time. The life of these patients was undoubtedly prolonged.

As for the immediate effect of the transfusion on the symptoms associated with the anemia, no method of transfusion could surpass the results of the citrated blood. The transformation in the patient is short of miraculous. I know of no condition in medicine in which the rapid change is so marked. A very annoying symptom often complained of most bitterly by patients is the peculiar "surging" noises in the head, keeping the patient from resting and possibly due to the diminished viscosity of the blood. With one of my patients this was the first sign that the anemia was increasing and this was always corroborated by a much lowered hemoglobin. This manifested itself on four different occasions, and with each of the four transfusions which followed, after about 600 c.c. of blood had run into the veins, these noises regularly disappeared.

Improvement in the other symptoms becomes evident after several days; in some cases sooner. The hemoglobin and red blood cells always increase; the general strength of the patients improves; so much so, that they are able to get out of bed and walk without becoming faint or breathless; the frequent disgust for food lets off; they even get an appetite, and the digestive disturbances disappear. The rapid pulse becomes slower; and in two instances in which loud systolic murmurs were present over the entire precordium prior to transfusion, the murmurs almost entirely disappeared after the transfusion, only to reappear again, however, when the severe anemia returned. In three instances in which the patients had mild temperatures for weeks previous to the transfusion, these subsided within forty-eight hours after the transfusion. This should not be taken as characteristic of pernicious anemia, as the same observation was made in transfusion for simple chronic secondary anemia after hemorrhage (anemic fever).

How long does this state of improvement after the transfusion last? Our only answer can be, "Nobody knows; we must wait and see." As was said before under the discussion of remissions, the improved state may last only for a week or as long as several years. One transfusion may not suffice. It may require two, three, four or even many more to bring about a lasting result. Naturally, it depends to a great degree on the type of case. There is a form of pernicious anemia which is acute, virulent and rapidly progressing, in which the condition is very serious and the patient tends to go down the hill quickly, no matter what is done. The physician bears the responsibility here in that the transfusion should be undertaken early and not until the general condition of the patient or the hemoglobin is so low that the nutrition and life of the tissue cells is undermined. It must be remembered that anemia itself leads to disturbed functions or even degeneration. It is surprising how quickly certain patients will lose ground.[1] On the other hand, it is just as surprising to see how comparatively well patients will exist with a hemoglobin as low as 12 per cent. and red blood cells as low as 800,000.

If a given transfusion has not brought about a remission or the patient has not improved quickly, another transfusion should be undertaken without delay, possibly from a different donor. Then, too, if a patient has improved and a remission has set in, transfusion should be repeated just the same as soon as the very first evidence appears that the patient is not holding his own either in his subjective general feeling or by examination of the blood. There is no limit to the number of transfusions a patient may receive, and I have in several instances given 1,000 c.c. of blood twice in three days. In some cases in which repeated transfusions are undertaken, it is surprising to note that the patients will usually do well for the same definite period of time after each transfusion, for example, one month, and then the symptoms will recur. Furthermore, the recurrence will usually be initiated in the same patient by the same train of symptoms; for example, in one patient it was always the surging noise in the head; in another it was the complete loss of appetite; in another it was the complete exhaustion, etc.

In this connection, we all know that the patients with pernicious anemia have an achylia gastrica. In one case I was able to do a test meal again after the transfusion, when the patient felt very well; but no free hydrochloric acid or pepsin was found. Even in a case in which splenectomy was performed and improvement had set in, a pre-existing achylia remained. The relationship between lack of gastric secretion and progressive anemia is a problem often discussed; but no conclusion has been reached as to which is primary and which secondary. In another case, the patient was seen with a blood picture and clinical appearance of pernicious anemia; but hydrochloric acid was still present. Later on the free hydrochloric acid disappeared. This would speak for the achylia as a secondary manifestation; rarely, however, do we meet the cases early enough to determine this question.

With regard to the quantity of blood, here too I am in favor of employing large amounts, from 900 to 1,000 c.c. of blood—the more the better. While it is true that in pernicious anemia the new blood is supposed to stimulate the blood-forming organs, we have noted cases in which there will be evidence of the rapid manufacture of red blood cells without an improvement in the symptoms. In such cases the well being of the patient may depend on how long the fresh supply of normal blood is kept without being destroyed; and naturally the more blood he receives, the longer it may last him. A smaller quantity of blood may suffice to start a remission or stimulate the blood-forming organs in some patients, but one never knows before the transfusion what type of case one is dealing with; and therefore, we are safest with a large transfusion. Naturally one must take into consideration the usual factors of size, age and condition of the patient.

In two instances, compatible blood was used from two patients suffering from chronic nephritis; the blood showed high figures for the nitrogenous constituents. Not only were no harmful effects noted, but the usual good result was obtained. It is of importance to know that such blood may be used in an emergency, especially for cases of acute hemorrhage.

During the entire treatment of the patients with pernicious anemia, the physician should constantly keep in mind that he must exhaust every means to detect any possible focal infection and overcome it. Dr. Barker places an enormous amount of importance on the teeth as the source of this infection. In this series, no such direct association could be attributed. My experience cannot quite corroborate the recent tendencies of making teeth infections the clearing house for man's ailments. The pendulum is swinging too high in this direction. On the other hand, they should always be eliminated as the cause of disturbances.

---

[1] In one patient the hemoglobin and red blood cells dropped to one third within two weeks.

In summary, it can be said without hesitation that the results obtained in pernicious anemia by sodium citrate transfusions are absolutely as favorable as those obtained by unmixed blood. In fact, the foregoing series compares almost identically with a similar series transfused with whole blood (Ottenberg and Libman). Furthermore, isolated instances can be cited in which sodium citrate transfusion seemed even more efficacious. Bernheim reports such a case. I, too, can add an example:

A woman, aged 50, received a direct transfusion of 900 c.c. of blood. An incision of the skin was necessary. Three weeks after, the severe anemic symptoms recurred, but the patient refused transfusion because of the difficulties associated with the operation and the lack of lasting improvement. A sodium citrate transfusion of 1,000 c.c. of blood was given in the guise of a medicated saline infusion; no incision was necessary. The improvement was so marked that the patient very willingly took another transfusion three weeks later. Two years have elapsed since then; the woman is up and about attending to her housework and apparently perfectly well.

It is too bad such favorable effects do not come more often.

LEUKEMIA

As for the therapeutic value of transfusion in cases of leukemia, the standard that is set by authorities who employed the unmixed blood is not very difficult to equal. Now and then a case with apparent distinct benefit for the time being is noted, but such improvement is short lived. In the present series, there were six transfusions in four cases of lymphatic leukemia, and one transfusion in a case of myelogenous leukemia.

One patient with acute lymphatic leukemia had severe bleeding from the nose and gums so that the loss of blood was becoming alarming. In addition, the patient had a high temperature. After the first transfusion of 600 c.c. of blood, the bleeding ceased, the fever came down, the hemoglobin rose from 28 to 60 per cent., and the patient felt much improved. This happy state of affairs lasted only for several weeks, when a renewed transfusion did not bring about a similar successful response. The high fever returned and the patient died.

A child, aged 3½ years, with chronic lymphatic leukemia showed marked improvement after a transfusion of 300 c.c. of blood. The change in the blood picture was very striking. The hemoglobin rose from 10 to 34 per cent.; the red cells increased from 1 to 2 million; the white blood cells decreased by 5,000 or more every day, so that three days after transfusion the leukocytes had diminished from 33,800 to 13,200; and whereas before the transfusion there were 100 per cent. lymphocytes, three days after the transfusion there were 28 per cent. polymorphonuclears. The general condition improved in the same striking way and kept up one week. Then another transfusion was given, but this time twice the quantity (600 c.c.). This may have been too much, as two days afterward there was dilatation of the heart and a slight edema of the lungs which ended fatally in five days. The blood picture, however, was remarkable: hemoglobin, 75 per cent.; red blood cells, 3,200,000; white blood cells, 7,200, and polymorphonuclears, 23 per cent.

I have mentioned these changes in the blood picture not because they are unusual, as they have been noted by other writers on transfusion. I merely wished to point out that sodium citrate transfusions accomplish this just as well as direct blood transfusions. No definite explanation can be given for the temporary halt in the disease or for the diminution in the white blood cells.

Another case of chronic lymphatic leukemia with severe bleeding from the gums and extensive gangrene of the roof of the mouth had no effect from a transfusion of 900 c.c. of blood. On the other hand, a marked benefit both clinically and hematologically was observed in another patient with chronic lymphatic leukemia of several years' standing. The diminution in the white blood count was not so evident (from 78,000 to 46,000), but the improvement in the general condition was much more striking.

Such immediate beneficial change was observed also in a case of myelogenous leukemia. After transfusion the fever dropped, the hemoglobin rose from 30 to 75 per cent., and the leukocytes diminished from 25,000 to 6,900. The patient's general condition was very much better, but one week after, he developed edema of the larynx and died.

In summarizing, blood transfusion is used in leukemia not with any idea of effecting a cure, but rather in the hope that the condition may be influenced to take on a more chronic form, with a resultant prolongation of life, or for the purpose of counteracting any acute complication or symptom associated with this dreaded disease. All this is readily accomplished by sodium citrate transfusion just as efficiently as by unmixed blood.

HEMORRHAGIC CONDITIONS

Under the heading of hemorrhagic conditions are to be found a number of different morbid conditions, having in common the one element of bleeding. Such hemorrhagic conditions include: (*a*) hemophilia; (*b*) hemorrhagic diseases of the new-born; (*c*) purpuras, and (*d*) secondary hemorrhagic diseases complicating such conditions as prolonged jaundice, grave anemias, leukemia and severe infections.

Some forms of bleeding are probably the result of infection, while others present developmental deficiencies of a serious order. Of the latter type, the most striking example is hemophilia, in which Howell has clearly demonstrated that the fault is to be found in a lack of prothrombin. It has been shown that transfusion of fresh blood favorably influences the cessation of the bleeding. The question that concerns us at present is whether blood mixed with sodium citrate can accomplish this just as well as whole blood.

The first patient, a boy, aged 14 years, was seen by me two days after the extraction of a molar tooth. Oozing had continued since the operation, and at the time of consultation the pulse was weak and rapid (136), the respirations increased, and the hemoglobin down to 56 per cent. All attempts to stop the bleeding were futile. The coagulation time of the blood was forty-eight minutes. Nine hundred c.c. of blood were transfused, and in six hours the bleeding had entirely ceased.

The second patient, a baby 2 days old, passed three large bloody stools. Fifty c.c. of the mother's citrated blood were given intravenously and the bleeding ceased.

The sodium citrate method is especially well adapted for this type of case; these babies are often brought to the hospital, and it is very practical to send an intern to the mother's home, where the blood is collected in citrate solution and thus transported to the hospital where it is given. Preliminary transfusion tests are unnecessary if the mother's blood is used.

Three patients with chronic jaundice from obstruction of the bile duct received transfusions of 900 c.c. of blood from eight to twenty-four hours previous to operation. The tendency to bleeding in this type of case is well known to surgeons. For several years we have been accustomed at the hospital to prepare these patients by administering to them from 200 to 300 c.c. of human serum subcutaneously during the forty-eight hours previous to operation. Either 50 c.c. three times a day or 75 c.c. twice a day was the usual routine. The results from this method have been very satisfactory. In the three cases in which sodium citrate transfusions were performed instead, the results as far as bleeding is concerned, were just as satisfactory; and there were several advantages: first, the entire technic was less complicated and, second, the patients had the additional advantage of a fresh supply of normal blood.

One patient with chronic jaundice from gall duct disease was operated on without preliminary transfusion or serum treatment. An oozing of blood from the wound started soon after the operation and continued for four days, when 800 c.c. of citrated blood were transfused. The bleeding at once began to diminish, and in three days it had ceased entirely.

Dangerous hemorrhages associated with two cases of leukemia (one from the nose and one from the gums) and two cases of pernicious anemia (one from the uterus and one from the mouth) ceased immediately after transfusion.

Thus, while the number of cases with hemorrhagic tendencies in this series is not very numerous, still the almost perfect results in all is sufficient to demonstrate clearly that the presence of sodium citrate mixed with the fresh blood does not interfere with the action of the latter.

AS A SUPPORTIVE MEASURE

Transfusions can be employed to a very great advantage as a tonic in debilitating conditions. Medicinal aid, such as iron and arsenic, prove valuable adjuvants, but only after transfusion, when the vitality of the tissue cells has improved. In patients with very little recuperative power, a long drawn out convalescence can be definitely hastened by transfusion; patients in a run down state about to undergo a severe operation can often be saved from fatal termination by preliminary transfusion; patients afflicted with an incurable disease and suffering from disturbances associated therewith can be spared their last days of misery and acquire comparative comfort by means of transfusions. Such and similar conditions were the indications in fifteen patients of our series.

Each of seven patients was given a transfusion preliminary to operation; two women very much weakened by long continued uterine hemorrhages withstood complete hysterectomies successfully; it is doubtful whether this would have been possible without transfusion.

Two patients with anemia due to repeated bleedings from hemorrhoids for years received 750 c.c. of blood previous to operation.

One patient with Banti's disease received a transfusion preliminary to splenectomy. In this particular instance I am almost certain that the patient would not have survived the operation. The anemia was of a very severe grade (32 per cent. hemoglobin); there was an associated endocarditis, and in addition there was a tendency to nasal hemorrhages and recurrent rises of temperature. In spite of these complications the operation and convalescence passed uneventfully.

A patient with carcinoma of the intestine withstood a difficult resection of several feet of intestine without any disturbance.

An extremely undernourished girl with sarcoma of the hip (afterward found to have general sarcomatosis), who had been in bed with high temperature for weeks, withstood without trouble a difficult hip resection.

Naturally, one cannot say absolutely what the results would have been in any of these instances had no transfusion been given; but one can be reasonably sure that some of the patients would not have recovered from the operation, and it is certain that their condition after the operation would have been more stormy. I am convinced that nothing more could have been accomplished by the transfusions of whole blood.

As a purely palliative tonic measure, transfusion was employed in eight instances; one case with inoperable carcinoma of the rectum; one case with general carcinomatosis of gastric origin and marked inanition; one case of biliary fistula; two cases of noneffective gastro-enterostomies; two cases of marked inanition from severe diarrhea, and one case of extreme malnutrition associated with a long drawn out sepsis following a pelvic abscess. None of these patients recovered; but nothing else could be expected because the underlying condition was one that could not be remedied. On the other hand, all the patients showed definite clinical improvement. As far as the sodium citrate question is concerned, one can with almost absolute assurance state that transfusions of whole blood instead of citrated blood would have offered no more favorable statistics. No type of transfusion can cure organic pathologic changes.

THE NEUTRALIZATION OF POISONS

The possibility that blood from a healthy donor may be employed to overcome the effects of various types of poisons was one of the earliest great expectations from transfusion.

Poisons may be thus subdivided:

(*a*) Bacterial infections with:
  Bacteremia:
    Endocarditis, infections with pyogenic organisms, typhoid, etc.
  Toxemia only:
    Diphtheria, etc.
    Peritonitis, etc.
(*b*) Chemical:
  Diabetic coma.
  Acute gas poisoning.
  Acute yellow atrophy of liver, etc.

BACTERIAL POISONS

As soon as the principles of immunity were more closely investigated, it was apparent that in bacterial infections, transfusion of blood was mainly of use for its general strengthening effect rather than for its specific bactericidal or antitoxic effect, because the normal blood usually has less specific antibodies than the infected individual. For this reason there has been advised the artificial immunization of donors against the specific infecting agent previous to transfusion. Not only do such immune donors have a great number of specific antibodies in the plasma (humoral immunity), but it is possible that on the basis of the cellular immunity, red blood cells share the powers of immunity with the other tissue cells; and thus, by transfusion, we are transferring immune cells which may continue to functionate.

Five patients suffering from subacute infective endocarditis were transfused. In one patient who had only eight bacterial colonies per cubic centimeter of blood before the transfusion, the blood culture became sterile and remained so for one week after the transfusion. A repeated transfusion from the same donor later on did not, however, bring about the same hoped for result; so that the transfusion cannot be definitely credited with the bacterial free state of the blood. One patient received blood twice from a donor previously immunized with the *Streptococcus viridans*, but no special effect on the number of colonies after transfusion was noted.

None of the patients ultimately recovered; but the transfusions had a very marked beneficial effect on all of them and undoubtedly prolonged life. Before the transfusion there was frequently no appetite and complete lack of strength, causing severe exhaustion at the least exertion. The change in the subjective feeling of the patients after transfusion was very pronounced. As one of my patients put it, it renewed his lease of life.

Infective endocarditis still leans toward the incurable class of diseases, so that transfusions from an immune donor should be undertaken as early as possible and not delayed until the poisons have affected the tissue cells too severely to react.

As for infections with pyogenic bacteria, there was a case of staphylococcus bacteremia associated with osteomyelitis. The patient was a boy, aged 12, with a bad infection of the tibia that resulted also in a severe grade of anemia (39 per cent. hemoglobin). Resection of the lower end of the tibia did not bring about a cure. Three weeks after, a transfusion (600 c.c.) was undertaken with a splendid result. Improvement started immediately, and in six weeks the patient went home, having gained 16 pounds in weight, with the hemoglobin up to 65 per cent. and the leg practically healed, almost ready to walk.

Not so brilliant, however, was the outcome in two cases of streptococcus (hemolytic) sepsis associated with intra-uterine infection. Repeated transfusions in both patients gave only a slight temporary improvement; the infections progressed rapidly to a fatal issue.

Such also was the result in a case of peritonitis following an appendectomy for a virulent gangrenous infection. The blood culture was sterile; but the general toxicity was extreme, and the patient died.

A child, aged 5 years, with diphtheria, who had received a large dose of antitoxin but in spite of which showed evidences of a severe toxemia (coma, albuminuria and bradycardia), was bled (300 c.c.) and then transfused with 300 c.c. of citrated blood. No change in the condition was noted, and the patient died.

Thus it is realized that much is still desired of transfusion as a therapeutic means for bacterial infections. This pertains not only to citrated blood, but also to whole unmixed blood. The use of immunized donors holds out greater hope, but statistics are still too few to permit a conclusive opinion.

As for chemical poisons, our experience is limited. A diabetic patient who had been operated on for gangrene of the foot suddenly developed severe diabetic coma. The ordinary therapeutic measures produced no effect. Venesection with removal of 500 c.c. of blood was followed by transfusion. The improvement was distinct; the patient revived from her coma but relapsed again in twenty-four hours. Venesection and transfusion were repeated, and while a noticeable improvement again occurred, the patient did not recover.

Similarly unsuccessful was the result in a woman suffering from toxemia following labor. Favorable results have been reported for the use of whole blood transfusions in gas poisoning. The present series does not include such an example, but there is no doubt that the action of citrated blood will be just as efficient as whole blood.

COMMENT AND SUMMARY

When transfusion was first introduced, it was grasped at as a cure for almost every disease. Accordingly, our disappointment was the greater when the hoped for did not materialize. At the present day, however, we have limited the indications and realize the shortcomings.

Absolute cure from infusion of blood can be ascribed to only comparatively few types of disturbances. It undoubtedly is a life saver in patients suffering from hemorrhage of whatever origin. This is being best demonstrated during this world struggle. In the numerous other conditions for which transfusion is given or advised, it is the most efficient means for prolonging patients' lives in comfort or for aiding them to recover much more quickly than they otherwise would. All these indications are fulfilled by the sodium citrate method of transfusion just as successfully as by the other methods of whole blood transfusion, and much more easily. In fact, it is the only means that is feasible under some circumstances, for example, the present day indications on the battlefield. Here large quantities of blood of each group can be held in readiness for any emergency and, if necessary, can be given in the field. The citrated blood will keep well for days or even weeks.

It is true that uncomfortable reactions follow infusions of citrated blood more often than unmixed blood, but in no way have these been harmful to the patient or interfered with the fresh blood's favorable effect. The cause of these reactions has not been definitely established. Several factors will probably have to be taken into consideration. I believe that some change occurs in one of the blood constituents, possibly the platelets or leukocytes. This results in the chill and the subsequent fever which resembles so closely the symptoms following intravenous administration of vaccines or proteins. In any event, all attempts should be and are being made to eliminate this reaction.

CONCLUSION

One hundred transfusions by the sodium citrate method have been performed for various disturbances, and the favorable results compare almost absolutely with those obtained by other authors using unmixed blood. It should, therefore, except only in special instances, be adopted as the routine method, since both the clinical and the laboratory findings support this view.

Terminal Disinfection.—Cleanliness, fresh air, proper care of the sick, correction of ill-considered personal habits are more to be commended than the potencies of various germicides, and such are more in accord with the tenets of preventive medicine.—*Weekly Bulletin*, Department of He
New York City.

ORIGIN OF THE SO-CALLED AUTO-INTOXICATION SYMPTOMS *

WALTER C. ALVAREZ, M.D.
SAN FRANCISCO

The cave man of the glacial period and the savage of today would doubtless agree that practically all disease is due to the malevolence of evil spirits. That idea constituted the first system of medicine. The next one appeared with the dawn of civilization, when men awoke to the possibility that some diseases might arise from spontaneous derangements of the bodily functions, particularly those concerned in excretion. hey reasoned that if feces are foul, then the body ust be in the best condition when freest from such material. This idea, which is based on what appears to be an obvious truism, has always been an attractive one, particularly to the lay mind. The ancient Egyptians purged themselves at certain times in the moon's cycle, just as many people now take calomel in the spring. For thousands of years, physicians have been in the habit of purging their patients when they have not known what else to do. We see, then, that the present day dread of stasis and "autointoxication" is nothing new. In the eighteenth century, the high priest of the cult was Johann Kämpf, who believed that all disease was due to impacted feces. Under his teaching the use of large medicated enemas became immensely popular, and the apothecaries fattened off the hypochondriacs then, just as the "internal bath" specialists do today.

The medical historian feels, therefore, that the ready acceptance of the views of Bouchard, Metchnikoff and Lane in the twentieth century must be due in large part to the fact that they fit into this great background of inherited belief. Still another factor in the rapid dissemination of these ideas has undoubtedly been the advertising campaign of those who would sell liquid petrolatum, agar, indigestible foods, sour milk, and patented syringes. One cannot blame the layman for his prompt conversion to what appears to him to be a sensible enough doctrine, but it does seem as if the scientific physician should look into the matter more carefully before he starts inoculating his patients with fear.

THE DIAGNOSIS OF "AUTOINTOXICATION"

I wish in this paper first to protest against the thoughtless way in which many of us are constantly making this diagnosis of "autointoxication." I do not deny that there may be such cases, but my experience in looking over the people who have been classified as such by other physicians makes me feel that the real article must be rare.[1] Time and again I have been put to the embarrassment of having to point out to some brother physician that his beautiful case of "autointoxication" was really an aortic regurgitation, a chronic nephritis, a myxedema, a high blood pressure, tuberculosis or some other well known disease. In the most recent of such cases, there was a hemoglobin of 45 per cent., a systolic blood pressure of 200 mm. of mercury and a large fibroid tumor of the uterus. The patient's physician was surprised to find that the constipation which he thought was primary and responsible for all her symptoms was really one of the least of her troubles. It undoubtedly is true, as Taylor[2] says, that fashions in the "cloak for ignorance" change just as they do for other wearing apparel. When confronted by puzzling cases, we probably will always have a tendency to fall back on stock diagnoses, such as "too much uric acid," "typhoid-malaria" or "disturbances in the autonomic nervous system." Just at present the popular fancy seems to turn to "autointoxication" and "focal infections."

There are a considerable number of men, however, who do examine their patients and who still believe, after finding nephritis, hypertension, arteriosclerosis or gastric ulcer, that these diseases are due, directly or indirectly, to intestinal stasis. Some persist in this view even when it is shown that the patient has no stasis. Such men, it seems to me, are hopeless and beyond the reach of argument. The others who have demonstrated abnormal stasis in their patients may be in the right; I respect their position, but I believe it is weak. When men like Alonzo Taylor[3] and Adami[4] with their great technical knowledge tell us that there is no real evidence to support the theory of intestinal toxemia, and that the pathologic findings can be explained more easily in other ways, it seems to me that we should be slow to accept the enthusiastic claims of rough and ready surgeons who have short-circuited a few colons.

UNPROVED ASSUMPTIONS

It is not sufficient to show that toxic substances can be formed during the bacterial destruction of nitrogenous matter. It must be shown that these toxins are formed in the intestine; that they can pass through the mucous membrane; that they can escape destruction in the liver; that they can reach the general circulation in amounts sufficient to produce symptoms, and that the symptoms produced by the repeated injection of small doses of these substances into animals are similar to those observed in constipated men. Unfortunately a review of the literature on these suspected toxins shows that little has been done with most of them beyond proving that they may be formed in vitro. Others, such as albumoses and peptones, are known to be present in the intestine; some of them are highly toxic when injected into a vein, but they are harmless when taken by mouth. The same thing may be said about many bacterial toxins. Filtered cultures of virulent cholera vibrios that will produce severe gastroenteritis and death when absorbed from the peritoneal cavity will have no effect when injected into the bowel.[5] We know also that antitoxins, secretin, epinephrin and other organic substances cannot be administered successfully by mouth. It is even more remarkable that such simple molecules as magnesium sulphate and lactose are practically unable to pass through the intestinal mucosa.[6] Many such examples could be quoted,[7] all showing how certain we must be on this point of absorption before we can ascribe the symptoms of "autointoxication" to any one substance.

Those who are impressed by the enormous numbers of bacteria found in the feces should remember that

nearly all of them are dead. Distaso[8] and others have pointed out that they cannot multiply in constipated feces on account of the dryness and the lack of nitrogenous food. Only in the cecum can a little peptone be found. It seems clear also that there are antibacterial forces at work in the bowel, and we must be very careful in drawing conclusions from the results of experiments in vitro. It must be remembered, moreover, that the great number of intestinal bacteria produce no soluble toxins. Even those that do produce toxins may do little harm because, as we have seen above, these substances are often unable to pass unchanged through the mucosa.

According to Mutch,[9] who has written one of the chapters in Lane's book and who is often quoted by those who believe in "autointoxication," the luxurious flora of the colon is a protective and useful mechanism in that it insures the rapid breaking down of amino-acids or other nitrogenous substances "into relatively innocuous bodies such as phenol, ammonia, water, carbon dioxid and hydrogen." To this list he adds later indolacetic acid, indoxyl and indol.[10] Mutch realizes also that in the colon there is even less chance for absorption of toxic substances than there is in the small bowel. He admits that there is no absorption demonstrable even when short circuiting changes the colon into a blind sac full of stagnating feces. We know from researches on nutrient enemas that practically nothing can be utilized besides water, salt and a little sugar.[11] We know also that the feces begin to harden in the ascending colon, and thereafter they undergo practically no churning movements. They tend to go forward through the remainder of the bowel like cars on a track. This fact is brought out not only by the roentgen ray, but particularly by the study of fecal masses, in which one can often see sharp lines of cleavage between residues from two different meals. Very little absorption can be expected under such circumstances. To get absorption the feces would have to be liquid and churned actively to and fro as are the contents in the jejunum.

THE EFFECTS OF STASIS

Many of the writers on autointoxication have recognized this difficulty and have struggled to evade it. Bouchard[12] felt that colonic stasis could do little harm, and he even went so far as to say that with the dying out of the bacteria in the hard, dry feces, "constipation ought to be regarded as a protection against autointoxication." He thought the poisoning was to be observed "in chronic diarrhea, in cancer of the stomach or intestine, in chronic dyspepsia and above all, in dilatation of the stomach. Whenever he could get splash sounds in a woman's stomach he ascribed all the symptoms or pathologic findings she had to "autointoxication." Since then, of course, the roentgen ray has shown us that the stomach rarely retains its contents long enough for any fermentation or absorption of toxins.

Combe[13] also admits that colonic stasis probably can have little effect on health, and that the stagnation and absorption must be looked for elsewhere in the tract. The roentgen ray has since shown us in thousands of constipated people that the colon is practically the only place in which stagnation does take place. In some cases there is a little delay of the contents in the last few inches of ileum, and in rare instances there is a little stagnation in the duodenum. I am willing to believe with Mutch and Lane that stagnation in the small intestine might give rise to the absorption of substances which ordinarily would be broken down in the colon or voided by the rectum. My experience makes me feel, however, that in nine out of ten cases the stagnation is not of sufficient duration to allow of much bacterial action. Moreover, any symptoms complained of by these people may be due to the chronic appendicitis which is so often the cause of the iliac stasis. I believe the duodenal stasis described by Jordan[14] is produced artificially by his giving the barium shortly after a meal. I agree with other observers that duodenal stasis is rarely seen, and that it probably has little to do with autointoxication. Mutch takes refuge in the terminal ileum as about the only place in which toxic substances can be formed and absorbed. There alone do we find a few "selected bacteria not too numerous and not too versatile in their chemical potentialities." He found, in a few of the short pieces of ileum removed at operations by Lane, a bacillus which forms from histidin a substance, beta-iminazolylethylamin, which markedly lowers the blood pressure when injected into animals. From observations in fourteen cases he felt he had "proved definitely" that this substance is responsible for the low pressure seen in some cases of autointoxication. He claims that an ileocolostomy frees the urine from toxic substances absorbed from the terminal ileum, although we know now that that operation usually makes the ileac stasis much worse than before.

There are other things in Mutch's articles that make one uneasy about accepting his conclusions, and now further doubt has been cast by the work of Mellanby,[15] who found that he could obtain beta-iminazo only with pure cultures of certain bacteria. Other organisms, when present, broke it down as fast as it was formed. It was not absorbed from the colon, but was rapidly destroyed there by relays of bacteria. He says the substance is such a powerful stimulant to smooth muscle that it must produce diarrhea and vomiting as soon as minute amounts are formed. He cannot believe that it has anything to do with constipation; nothing short of a mechanical obstruction would keep the bowel from voiding it immediately. If beta-iminazo has any clinical significance he thinks it is in the vomiting and diarrhea of children!

NEED FOR SCRUTINIZING RESEARCH REPORTS

I have gone into the subject thus at length to show how carefully we must study the reports of research workers before we quote them in support of a favorite theory. Some of my friends who believe that autointoxication produces high blood pressure say, "Hasn't some one found a pressor substance in the intestine?" I believe not. Dale and Dixon have suggested that three amins closely related structurally to epinephrin may be formed from protein during intestinal putrefaction. One of these substances, parahydroxyphenylethylamin, has much to do with the pharmacologic actions of ergot. It seems to me unlikely that these substances have anything to do with hypertension as we see it in practice. If they were responsible for the increased pressure we would expect it to drop to normal after purgation or during periods of normal intestinal activity. Such, I feel certain, is not the case. Moreover, Dale and Dixon found that these drugs when given repeatedly soon lose their effect, whereas we know that hypertension tends to become progressively worse. Mutch has suggested indolethylamin as the cause of hypertension, but Laidlaw and Ewins have found that it is destroyed in the liver before it can do any damage.[16]

Friends have pointed also to the work of Whipple on the proteose intoxication from closed loops of intestine. They have said, "How about that? There you have a toxin formed during stasis." If they had read the articles referred to they would have found that Whipple's work does not favor their theory. The toxin is not formed in the colon at all and very slowly in the lower ileum. Dogs with closed loops of ileum or colon may live long in perfect health. Moreover, the substance is not absorbed from the lumen of the intestine, but from the mucosa where it is formed.

The cure for all this is more reading, and particularly reading of the original articles. Many who now look up to Bouchard, Combe, Metchnikoff and Lane as great masters to be revered would be cured of their belief in "autotoxemia" if they would only read the hodgepodge books these men have written on the subject. Whenever I look into them I am reminded of the boy who had to write a composition on the horse. He began by remarking that the horse looks very much like the cow, and continued with a long description of the latter animal. Bouchard[12] rambles on about uremia, typhoid, diabetic coma, crude experiments to show the toxicity of urine, etc. Combe's carelessly written and pseudoscientific work[13] reveals a children's specialist who has become so used to ascribing the many symptoms of his little patients to the bacterial decomposition of food in their intestines that he cannot keep from looking at adults in the same way. We must remember that, as compared with the infant's digestive tract, the adult's is very much less sensitive in every way, and the mucosa apparently much less permeable to toxins and bacteria. Moreover, the acute upsets of the infant with diarrhea, vomiting, fever and rapid wasting are very different from the chronic constipation, headache and nervousness of the adult. Many of Combe's ideas as to autointoxication in infants may be correct, but he has no right to talk about babies in one breath and adults in the next, as if there were no difference between them. One must object, moreover, to his reliance on the old worthless experiments in which urine and feces from the supposed victims of "autointoxication" were injected into the veins of rabbits.

We know now that Metchnikoff[17] was wrong about his lactic acid bacilli, and that they do not even survive in the colon; much less do they replace other forms.[18] It seems likely from recent work that the earlier writers, with their imperfect cultural methods, fed one bacterium by mouth and recovered another closely related saprophyte from the stools.[19] Most of the patients who come to me with intestinal troubles have already been thoroughly dosed with fermented milk, and I cannot see that it does them much good. Occasionally it helps because of its laxative properties, or perhaps on account of the lactose which favors the growth of a nonproteolytic flora in the bowel.

Half of the space in Lane's book on intestinal stasis[20] is taken up with some old articles of his on bone and joint deformities. He believes that these things throw light on the formation of bands and membranes in the abdomen; but the recent findings of anatomists and embryologists are all against him. It appears now that these bands are not due to the sagging of overloaded colons or to chronic infection, but to congenital defects in the rotation of the bowel and in the cleavage of peritoneal layers.[21] They are just as common in fetuses and infants as in adults. We have learned that kinks are normal features of the bowel; that adhesions often do no harm, and that enteroptosis is normal and innocuous in a large proportion of men and women. Lane's operations have also been discredited. We know that an ileosigmoidostomy does more harm than good, and that the colon is not a useless organ that can easily be removed.

We see from all this that although there are many clinical facts which strongly suggest that poisons are absorbed from the digestive tract during constipation, we have as yet very little actual proof for this assumption. It is far easier to believe that toxins are absorbed in the presence of diarrhea, dysentery, typhoid or the gastro-enteritis of children. In some of these conditions, however, the toxic symptoms may be due not only to chemical substances, but also to the actual invasion of the mesenteric lymph nodes and blood by bacteria.[22] Schloss[23] has just shown also that the poisoning in children with vomiting and diarrhea is often uremic in nature. Dehydration leads to imperfect excretion and also to a rise in the nonprotein nitrogen of the blood.

SYMPTOMS NOT DUE TO TOXINS

I wish now to limit the discussion sharply to a certain type of case in which I can say confidently that the symptoms are not due to the absorption of any toxin. These are the people who come in complaining of a constipation which they feel sure is undermining their health and keeping them from a full use of their faculties. I am sure there is nothing imaginary about their symptoms, which certainly can be very annoying. The principal one is often a mental haziness, a "dopiness," or a feeling of having been drugged. In addition, they may have malaise, headache, spots before their eyes, a coated tongue and a poor appetite. Now, although I have already pointed to some of the things which make me slow to accept the doctrine of "autointoxication," there is one fact which alone would convince me that the symptoms complained of by these people are not due to the absorption of toxins. On being questioned, they practically all admit that these symptoms are relieved instantly by a bowel movement. My attention was drawn to this point years ago by a friend who worked in an adjoining office. He would often say to me, "It's no use; my brain is in a muddle; I am dizzy and my head aches so I cannot see; I will quit for the afternoon and go home." Ten minutes later he would return, perhaps whistling cheerfully, and would remark on the fact that an unhoped for bowel movement had promptly relieved him of his discomforts. I could go on to quote scores of such cases; cases which I am sure would convince any physiologic chemist that the symptoms were not due to circulating toxins. He would know that in that case relief would not follow immediately after removal of the source of the poison but later, when sufficient excretion had taken place to lower greatly the concentration of the substance already in the blood. We know that with normal kidneys a man will take two hours to get rid of perhaps 65 per cent. of a dose of phenolsulphonephthalein injected into his muscles. The layman appreciates this point best when he is reminded that after eating asparagus it takes him from twelve to fifteen hours to excrete most of the aromatic substance that is noticeable in the urine. A search through the literature shows that several men have commented on this sudden relief from symptoms and have recognized the impossibility of dragging in a chemical theory to explain them.[24]

EFFECT OF DISTENTION OF THE LOWER BOWEL

But if these symptoms are not produced by toxins, what are they due to? I feel sure that they are caused by the mechanical distention and irritation of the lower bowel by the fecal masses. Perhaps the best proof of this assumption is to be found in the observation made by my friend Dr. Saxton T. Pope that in these people the classical symptoms of "autointoxication" can be produced by inserting a cotton tampon into the rectum. I have since observed the same thing with masses of barium and with cacao butter suppositories. One woman experimented on was so upset by the presence of a suppository in her rectum that she dug it out with the handle of a spoon. She often had to do the same with small fecal masses, which nearly drove her crazy. Years ago, Leube[25] found that the pressure of his finger in the rectum was sufficient to produce typical symptoms in some of his patients. Zimmermann[26] found also that the rectum is exceedingly sensitive to pressure. Changes of from 2 to 3 mm. of mercury were perceived, and a rise of from 20 to 60 mm. caused distress.

The trouble with these people who complain of "autointoxication" is that they are unduly sensitive and keenly aware of what is going on in their bodies. I often ask such women if they could do any mental work with a flea crawling on them. They generally answer, "Certainly not. I would have to stop everything and get rid of it." Similarly, I know business men who will drop everything at the office and rush home to take an enema. It is this sensitiveness which distinguishes these people from those who are not worried or upset when their bowels fail to move.

There should be no difficulty in accepting these views when we remember how profoundly sensory impulses from our digestive tracts can influence our emotions, our mental processes and our vasomotor balance. Thus the sleepiness and mental hebetude which worry the "autointoxicated" are experienced by many people after dinner. We do not ascribe that to the absorption of poisons. It may be due to the absorption of food, but some observations on a man with a jejunal fistula made me think that it may be due solely to the distention and the increased activity of the bowel. I was led to this conclusion by the fact that the man would go to sleep when the intestine was made to contract actively on a small balloon inserted through the fistula. We know too that active intestinal contractions can slow the pulse and sometimes produce sweating.[27] They seem also to have something to do with dreams and nightmares. Similarly, hunger with its powerful gastric contractions can put a stop to all mental work and can make the subject restless and irritable. Some people suffer from headache, dizziness and nausea which can be relieved instantly by the taking of food. Carlson has shown that these symptoms are intimately associated with the hunger contractions. When the contractions are taking place the knee-jerk is more active.[28] Dmitrenko[29] accelerated the respiration and pulse in dogs and raised their blood pressures by stimulating the stomach in various ways, as by distention with balloons.

The faintness, dizziness, pallor and cold sweats of nausea, sudden diarrhea and flatulent distention are all due to the vasomotor upsets observed by Carlson in his work. Any one who has ever given an anesthetic to a person with a full stomach must have marveled at the wonderful difference between the state of circulation and respiration before vomiting took place and afterward. I have been impressed at times by the great mental depression occasioned in some patients by the presence of a duodenal ulcer[30] or by a small fissure in the anus. Surgeons are well acquainted also with the tremendous respiratory reflex that follows dilatation of the anal ring.

We see, then, that particularly in sensitive people the brain is profoundly influenced by afferent impulses coming from a distended, overactive or wrongly acting bowel. The effects follow so closely on the appearance and disappearance of the stimulus that we cannot drag in a cumbersome and roundabout chemical mechanism to explain them; they must be produced directly through the nervous system.

As I have pointed out in another paper,[31] many of the symptoms of constipation are due simply to the plugging of the lower end of the canal, which slows or stops the downward current and often produces ripples of reverse peristalsis. The food cannot go downward, so the bowel tries to refuse it admittance or sends it back again. Thus, intelligent people have told me how the removal of the rectal plug has often given them immediate relief from regurgitation and belching. I believe that the distended and active colon sends off ripples which run up the bowel and break into deeper waves in the upper part of the stomach and esophagus. These waves can carry more than the usual amount of bile back into the stomach and up into the mouth and give rise to the term "biliousness." They account also for the lack of appetite and the feeling of fulness after eating a few mouthfuls. It has been shown that they deposit gastric and perhaps intestinal contents on the back of the tongue, and in that way give rise to the coat on that organ, the bad taste and the bad breath. The relief obtained by taking calomel is not due to any hypothetic action on the liver, but, I believe, to a restoration of the normal downward currents.

OTHER CAUSES OF SYMPTOMS

One must always make sure in any particular case that the symptoms complained of are really due to constipation and not to cardiovascular disease, tuberculosis or something else. A careful history often shows that overwork, worry and lack of sleep give rise to the symptoms and finally to the constipation. I have in another paper[32] given some of my reasons for believing that nervousness is generally the cause and not the result of constipation.

Although attacks of migraine, scintillating scotoma, dizziness, etc., may often be associated with constipation and sometimes warded off by purgation, many of my patients who have been induced to keep careful records have found that the attacks were really just as frequent when their bowels were well cleared or working normally. Many of them have discovered also that the spells are likely to come more frequently after periods of fatigue, excitement, worry and the loss of sleep. A number of these people have returned after months or years to tell me that the constipation was gone and the symptoms no better. Others remember that they had the symptoms during childhood when their bowels moved perfectly. It is significant that other members of the family often have the same symptoms without the constipation. Several years ago Franz[33] made a very careful metabolic study of a patient with migraine, and could find no change in the constituents of the blood during the attacks. He was forced to conclude that the disturbances arise in some part of the brain much as they do in epilepsy. I believe the gastro-intestinal upsets are secondary and comparable with those seen with brain tumors. In one of my patients attacks of petit mal sometimes take the place of his migrainous headaches. Some patients have been greatly helped by the removal of diseased appendixes. They still have the headaches, but these come less frequently and the gastro-intestinal symptoms are less marked.

In the worst of these cases of "autointoxication," the sufferers are undoubtedly psychopathic. I have learned to recognize the type at the first interview, and I no longer waste much time with them, as it is practically impossible to change their habits of thought. They are generally of neurotic or insane ancestry and often give a history of "nervous breakdowns" in the past. Nowadays they come in with a box full of roentgen-ray plates, and their estimate of the ability of the physician rises or falls with the number of kinks which he can discover in them. These people want to do all the talking, and arguments make no impression on them. Artful questioning will often elicit the fact that they have from one to six movements a day, but these are not large enough; they are not shaped properly and their expulsion does not leave the desired feeling of comfort and rectal emptiness. After great and prolonged exhortation, they may promise to leave their bowels alone for forty-eight hours, but when they return they admit that they became worried and thought there would be no harm in their taking some castor oil the first night, a dose of salts in the morning and several enemas along the way.

Some of my confrères maintain that this mental aberration is due to long-continued poisoning, but I cannot believe that when I learn that these people were hypochondriacs before they became constipated. Why can we not forget the colon and glands of internal secretion long enough to let the brain have a few diseases and hereditary defects all its own? Those of us who are not alienists seem to have the idea that all crazy people are plainly insane, and all locked up in asylums. Nothing is farther from the truth, and the gastro-enterologist must constantly be on the watch for borderline cases.

In chatting with medical friends it is interesting also to learn that the same individuals, when they do happen to get over their colonic phobias, show up at the oculist with floating spots, queer failures of accommodation, unbalanced external muscles, etc. They go to the genito-urinary man for sexual troubles and "lost manhood," and to the orthopedist with hysterical joints and weak backs. These people are unending sources of income to the enthusiasts in all specialties, to the unscrupulous, the reckless operators, the osteopaths and the quacks. The honest physician who admits his failure to find anything physically wrong is discredited and soon discharged, often without payment for his trouble.

TREATMENT

Some may say now, "Well, you admit the reality of the symptoms, you admit that they are often caused by constipation and that they can be relieved by clearing the bowel—what difference does it make whether they are ascribed to autointoxication or to nervous agencies?" My answer is that it makes a tremendous difference. In the first place, as scientific physicians, we must seek the truth; if the facts of the case support the mechanical and nervous theory and not the chemical one, we must follow the facts. In the second place, the new idea is invaluable when it comes to treatment. The old theory produces hypochondriacs; the new explanation may set them free. Only by coming to believe in it can they regard their colonic functions as unconcernedly as does the normal man, and that is the first step toward a cure.

A case showing clearly the harmful effects of the old teaching and the helpful effects of the new came to my attention about two years ago, when a prominent business man, a big, athletic fellow, told me this story:

> He had been perfectly healthy until six years before, when the fear of approaching baldness led him to consult a well-known dermatologist. The doctor told him that baldness was due sometimes to "autointoxication," and asked if he was constipated. He said he never had been, but this did not discourage the physician, who suggested that stasis might still be present and the bowel movements insufficient. This sounded plausible, so the patient began to take cathartics every day. Before long he was going from physician to physician in

search of stronger purgatives. He saw a prominent internist who found what he thought were pronounced abnormalities in the colon and gave a gloomy prognosis. Later he went to a well known surgeon, who promised to cure him by removing his appendix. There never had been any symptoms referable to that organ, put the patient was now desperate and ready for anything that might put a stop to an intoxication which he had been led to believe would sooner or later undermine his mental powers. The operation brought no relief, and the surgeon explained that there were so many Lane's kinks that only a colectomy would now offer any hope. It was in regard to the advisability of this procedure that he consulted me. I found him a nearly perfect specimen of humanity with as normal a digestive tract as one could wish to see. What stasis he had was in his rectum. Sunday morning when he didn't have to rush for his train, he generally had an unaided bowel movement, which was the main event in his week. I suggested that if he would leave his bowels alone he might go back again to the normal condition from whence he had started. After several hours of argument he agreed to my proposal. His bowels moved after three days of anxious waiting, and they have been moving satisfactorily ever since. His colon no longer dominates his mental processes, but has receded into the background where it belongs. He still feels the classic symptoms at times, but they do not bother him any more, because the element of fear is gone. Now that he knows that no harm is being done to his body, he is perfectly willing to leave his colon to its own devices. Many others who have been cured in the same way tell me that it was only this fear that made them act so foolishly about their bowels.

Such cures can be obtained only with intelligent, well-balanced people who can follow an argument, stick to a course of action and, if necessary, suffer a little discomfort before attaining their end. If after a thorough trial it appears that the bowels will not move spontaneously without occasioning too much distress, the patient may use liquid petrolatum, agar or stewed fruit. Many of these people have such irritable, spastic colons that they cannot be helped at all if they continue to use bran and other coarse foods. These substances upset digestion and lead to the formation of gas. If an extra stimulus is essential, as it seems to be in some people, I am sure it is preferable, unless the patient has the digestion of an ostrich, to give a mild chemical stimulus rather than a rough mechanical one. I cannot understand why some physicians warn their patients against enemas. It seems a shame to upset 24 feet of intestine with a purgative when the material to be removed is in the rectum or sigmoid within easy reach of a little water.

These "autointoxicated" people are often so anxious to find a royal road to recovery that they are ready to be operated on by any surgeon who will promise a prompt and complete cure. My experience has taught me to avoid operations on such patients even when the roentgen ray shows the presence of distinct abnormalities. They are so sensitive that the surgeon can hardly leave the abdomen in such perfect condition that they cannot continue to feel something.

SUMMARY

"Autointoxication" is commonly diagnosed when a physical examination would show other more definite causes for the symptoms. Those who believe that intestinal stasis can account for a long list of disease conditions have little proof to offer for their views. Many of the assumptions on which they rest their case have been proved to be wrong.

The usual symptoms of the constipated disappear so promptly after a bowel movement that they cannot be due to absorbed toxins. They must be produced mechanically by distention and irritation of the colon. They occur in nervous, sensitive people. It has been shown that various activities of the digestive tract can profoundly affect the sensorium and the vasomotor nerves. The old ideas of insidious poisoning lead to the formation of hypochondriacs: the new explanation helps to cure many of them.

COMPARATIVE RESULTS OBTAINED IN THE TREATMENT OF PULMONARY TUBERCULOSIS

HUGH M. KINGHORN, M.D.
SARANAC LAKE, N. Y.

I. BY GRADUATED LABOR, AS EMPLOYED AT THE BROMPTON HOSPITAL SANATORIUM AT FRIMLEY, ENGLAND

The treatment of pulmonary tuberculosis by graduated labor has been systematically carried out at Frimley, England, for a number of years, and this method of treatment has had considerable influence on a number of lung specialists in this country. Dr. Marcus Paterson was in charge of the sanatorium at Frimley during the early years of its existence, and it is largely due to his work and writings that graduated labor has been used in England and America. Of the patients treated at Frimley, a great majority first passed through the wards of the Brompton Hospital in London, whence, if found suitable after a period of observation, they were drafted on to the sanatorium. They were not chosen at random; still less was every case of pulmonary tuberculosis at Brompton passed on in turn; on the contrary, the cases were carefully selected, only those patients being chosen who were free from fever or other constitutional symptoms, who possessed considerable vitality, and who had begun to show signs of improvement. So far as possible, also, patients with signs of limited disease were preferred, although it was soon found that patients with extensive disease, but of a quiescent type, often did remarkably well.

I was struck with two prominent facts while reading Paterson's book.[1] The first was that he paid more attention to the physical condition of his patient than he did to the foci of disease. He repeatedly emphasizes the fact that the physical condition is of much greater importance than an examination of the lungs. The second fact was the great importance he placed on the auto-inoculations that were obtained from exercise and work. These two facts are absolutely opposed to my interpretation of the modern method of treating pulmonary tuberculosis. In my judgment, a physical examination of the lungs is the only sure way that one can get a knowledge as to how the foci of disease are acting. It is a common occurrence to have patients consult us who are in good muscular physical condition and at work, and yet we find a slowly progressing disease. It is impossible to know how the disease is acting without a careful physical examination of the lungs. My principal object in treatment is to treat the foci of disease, but not to neglect but also treat the general physical condition. My chief aim is to change an open into a closed tuberculosis or an active into an inactive one. I believe that this is accomplished more surely and with better permanent results by rest than by graduated labor. I am quite aware that Paterson gave bed rest treatment to his patients with active disease, but when these cases became quiescent, he paid more attention to the physical condition than to the lung condition.

---

[1] Paterson, Marcus: Auto-Inoculation in Pulmonary Tuberculosis, London, James Nisbet & Co., 1911.

The second fact that Paterson emphasized very strongly was the value of the auto-inoculations obtained from graduated labor. This is also absolutely opposed to my interpretation of the modern treatment of pulmonary tuberculosis. My aim is to avoid auto-inoculations in every way possible, and to get the foci of disease quiescent as quickly as possible. Auto-inoculations are the results of congestion of the foci in the lungs, and it is just these congestions which are extremely dangerous and which we should try to avoid. We have no known way of controlling auto-inoculations, and it is a well known fact that one severe overexertion will sometimes cause such a serious congestion of the disease as to produce a fatal result. It is my firm conviction that the attempt to treat pulmonary tuberculosis by means of auto-inoculations is extremely dangerous and absolutely contrary to the safe method of placing the foci of disease in a quiescent condition as quickly as possible and keeping them quiescent.

II. BY BED REST TREATMENT

Bed rest treatment has been carried out very successfully by Dr. Joseph H. Pratt[2] of Boston. His results were obtained in the homes of the sick poor in a supposedly unfavorable climate. Supervision was maintained by the class method. There was no selection of cases. In 36 per cent. the disease was far advanced when the rest treatment was begun. The average duration of bed rest treatment was about four months, and the duration of graduated exercise combined with bed rest from four to seven months, making the usual duration of treatment from eight to eleven months. A few patients were not allowed to take regular exercise for from one to two years. Strict obedience to the rules was required. In tabulating the results, Pratt included those who were dismissed because they did not follow the rest treatment faithfully, those who left the class voluntarily, and those who died while taking the treatment. Eighty-eight per cent. of those admitted in the first stage were well and working from one to ten years after their discharge, 62 per cent. of the second stage, and 20 per cent of the third.

TABLE 1.—EMMANUEL CHURCH TUBERCULOSIS CLASS: STAGE OF DISEASE AND CONDITION OF ALL CASES, FROM ONE TO TEN YEARS AFTER DISCHARGE, INCLUDING THOSE WHO DIED WHILE UNDER TREATMENT IN THE CLASS *

Stage	Total Number	Per Cent.	Condition, July, 1916			
			Well	Living	Dead	Per Cent. Well
I	67	35	59	2	6	88
II	55	29	34	2	19	62
III	69	36	14	9	46	20
Total	191	100	107	13	71	

* Seventy-six per cent. of the first and second stage patients were well. No first stage patients died in the class. All the cases were traced.

In the period of ten years ending in July, 1915, Pratt treated 191 patients. The condition of these patients from one to ten years after their discharge is given in Table 1.

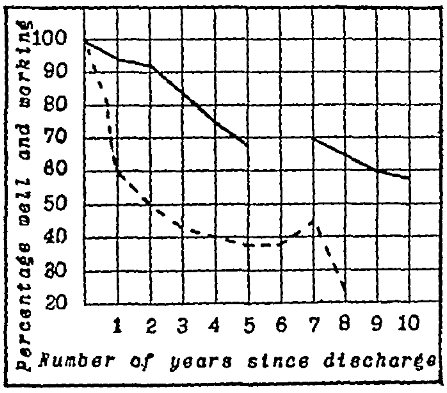
The cases selected for the comparison of the effect of prolonged bed rest with graduated work are those in which the wage-earning power had been restored while under treatment (Table 2 and chart). Many of the patients treated by Paterson at Frimley did five hours of hard labor a day before leaving the sanatorium without any apparent ill effect. After returning to work, a large number of them broke down within the first two years. The rapid drop in the percentage of patients well and working is well shown on the chart in the sharp and sudden drop from 100 per cent. at the beginning to 62 per cent. at the end of one year and 50 per cent. in two years. In Pratt's cases, there was a drop from 100 per cent. at the beginning to 95 per cent. at the end of one year and 92 per cent. at the end of two years. Pratt's figures show very clearly the important fact that strengthening a man's muscles and improving his general condition by graduated labor is not the best way to heal the tuberculosis foci in the lungs. His chart and tables clearly show that prolonged rest leads to permanent recovery in a large proportion of the cases treated.

TABLE 2.—AFTER-CONDITION OF PATIENTS WITH TUBERCLE BACILLI IN SPUTUM, DISCHARGED WITH WAGE-EARNING POWER RESTORED *

Number of Years after Discharge	Brompton Hospital Sanatorium; Treatment, Graduated Labor				Emmanuel Church Tuberculosis Class; Treatment, Prolonged Bed Rest		
	Total Number of Cases	Number of Cases Minus Those Lost Sight of	Number Working	Per Cent. Working	Total Number of Cases	Number Working	Per Cent. Working
1	1,051	965	593	61	42	40	95
2	1,051	868	434	50	39	36	92
3	741	581	265	46	39	34	87
4	475	341	153	44	38	29	76
5	292	209	81	39	34	24	71
6	150	96	40	42	32	22	69
7	39	22	5	23	30	21	70
8	....	...	...	..	20	14	70
9	....	...	...	..	14	9	64
10	....	...	...	..	8	4	50

* Of the Brompton patients, those lost sight of have been deducted in determining the percentage working. There were none lost sight of in the Emmanuel Church tuberculosis class.

At the end of one year, after discharge, there were 595, or 81 per cent., of the Brompton patients and forty, or 95 per cent., of the Pratt patients well and working. At the end of the seventh year, there were five, or 33 per cent., of the Brompton patients and twenty-one, or 70 per cent., of the Pratt patients well and working.



Patients with tubercle bacilli in sputum discharged with earning power restored; solid line, Emmanuel Church tuberculosis class; broken line, Brompton Hospital Sanatorium.

The results obtained by Pratt illustrate the great value of rest treatment over graduated labor. Pratt's figures also demonstrate another very important fact, namely, that patients who undergo prolonged and intensive rest treatment do not tend to relapse.

---

[2] Pratt, J. H.: The Importance of Prolonged Bed Rest in the Treatment of Pulmonary Tuberculosis, Am. Rev. Tuberc. 1:637, 1918; The Class Method of Treating Consumption in the Homes of the Poor, J. A. M. A. 49:755 (Aug. 31) 1907.

It is the constant experience of most physicians who treat pulmonary tuberculosis at health resorts that the home treatment of the disease is most frequently extremely bad. As a rule, the specialist at the health resort is more skilled than the physician in the city in the treatment of this disease, and the routine of the open air treatment can be carried out much better in the sanatorium or health resort than at home. Pratt's results, however, show that he obtained results at home by his bed rest treatment which are superior to those obtained in the same climate at the Rutland Sanatorium[3] in Massachusetts, and at the Massachusetts State Sanatorium. His results are also equal to those obtained at the Trudeau Sanatorium at Saranac Lake, N. Y.,[4] and at the Laurentian Sanitarium at Ste. Agathe des Monts, P. Q., Canada.[5]

The patients at Rutland Sanatorium in Massachusetts were drawn from Boston and its suburbs and lived, when at home, under the same social and economic conditions as did Pratt's patients. Rutland Sanatorium, although limited to favorable cases, had less than 25 per cent. of its patients well and working from eight to ten years after their discharge, while 59 per cent. of Pratt's patients were well and working after this length of time.

Among a large series of patients from Boston and vicinity who were treated at the Massachusetts state sanatoriums, Miss Farmer[6] found that 24 per cent. were well from four to seven years after their discharge. Of Pratt's patients, there were 63 per cent. who were well from four to seven years after their discharge.

III. REST AND EXERCISE AS EMPLOYED BY MOST SANATORIUMS

I will now briefly compare the results obtained by graduated labor with those obtained by the modern rest and exercise treatment, as employed at most sanatoriums. For purposes of comparison, I will take two sanatoriums which use rest and exercise, but do not allow their patients any manual labor. The exercise consists of walking exercise practically entirely. These two sanatoriums are the Trudeau Sanatorium and the Laurentian Sanitarium. The class of patients admitted to these institutions is the same, and the methods of treatment are identical. Rest treatment is used very thoroughly where indicated, but not so intensively as employed by Pratt.

TABLE 3.—CONDITION OF ADIRONDACK COTTAGE SANITARIUM PATIENTS FROM ONE TO TEN YEARS AFTER DISCHARGE (1903-1916)

Stage	Number of Patients	Well	
		Number	Per Cent.
I.	719	515	72
II.	1,166	669	57
III.	44	11	25
Total	1,929	1,195	

By taking an average of the percentages for the seven years of the Frimley results, we find that 44 per cent. of the patients discharged during a period of from one to seven years were well and working. Table 3 shows that during the period of from one to ten years, the Adirondack Cottage Sanitarium (Trudeau Sanatorium) shows that 61 per cent. of patients were well and at work. Table 4 shows that 56 per cent. of the patients who were discharged from the Laurentian Sanitarium were well and working during a period of from one to nine years.

Here again we have convincing proof that rest treatment is much superior to graduated labor treatment.

TABLE 4.—CONDITION OF LAURENTIAN SANITARIUM PATIENTS

Of 558 patients who have been treated in the Laurentian Sanitarium for a period of thirty days or longer, since 1908, 529 have been traced, and are thus classified: *

	Number	Per Cent.
Living and leading active lives	295	55.76
Still invalided	101	19.65
Total living	399	75.4
Died	130	24.6
	529	100

* Twenty-nine patients could not be traced.

It still remains to compare the intensive bed rest treatment as employed by Pratt with the usual rest and exercise treatment. We see from Table 1 that Pratt had a total of 191 patients, and that of these 107, or 56 per cent., were well from one to ten years after discharge. The Adirondack Cottage Sanitarium (Trudeau Sanatorium) had a total of 1,929 (Table 3), and of these, 1,195, or 62 per cent., were well from one to ten years after discharge. The Laurentian Sanitarium (Table 4) had a total of 558 patients, and of these, 295, or 55.76 per cent., were well from one to nine years after discharge.

It is thus seen that the results obtained by the intensive bed rest treatment as employed by Pratt are practically the same as those obtained by the ordinary treatment of rest and exercise as employed at the Adirondack Cottage Sanitarium and at the Laurentian Sanitarium. A critical examination of Pratt's bed rest treatment and the usual rest treatment shows that the two methods are practically the same. Pratt employs bed rest treatment to all his patients, and the others employ it only when indicated. The difference is, therefore, only one of degree. The results are the same.

Causes of Declining Birth Rates.—It is now well recognized that the fall in the birth rate is due chiefly, if not entirely, to the volitional restriction of the size of the family, that is, to the adoption of birth control principles. There are good grounds for believing that among the thinking classes of the community a majority of married couples limit their families by one means or another. Moreover, there is evidence that among this class the average size of the "limited" family is larger rather than smaller than that of the "unlimited" family. The explanation of this apparent paradox is, of course, that those couples with naturally low fertility have no need for limitation, whereas those with naturally high fertility are the most likely to resort to it. I would suggest that the fall in the birth rate is due to a reduction in the number of large families rather than to any great increase in the number of small ones. I think it very doubtful whether any appreciable number of childless marriages are due to the practice of birth control.—C. Killick Millard, M.D., D.Sc., *Journal of State Medicine.*

TWENTY-SIX CASES OF HYPERTROPHIC STENOSIS OF THE PYLORUS IN PRIVATE PRACTICE

WITH OPERATION BY THE RAMMSTEDT METHOD *

CHARLES GILMORE KERLEY, M.D.
NEW YORK

During the past four years twenty-six of my private patients with pyloric stenosis have been operated on by the Rammstedt method. Twenty-four were operated on by Downes at the Babies' Hospital, one by Downes at St. Luke's and one by Jennings at the Brooklyn Hospital.

In the cases reported, seventeen were boys and nine were girls. The sex in my series of cases agrees with the observation of Still, who reported that among forty-two cases, thirty-five were males. Ibrahim found boys affected four times as often as girls.

Thirteen patients represented the first pregnancy, six the second, five the third, one the fourth and one the fifth. In one, a second pregnancy, the first-born also had pyloric stenosis and died after gastro-enterostomy. All were full-term infants.

The ages at the time of operation ranged from 3 to 16 weeks. Fourteen were 6 weeks old or less, four were under 4 weeks, eight were from 6 to 11 weeks, and five were from 11 to 16 weeks.

The lowest weight at operation was 4 pounds, 2 ounces; the birth weight was 5 pounds, 8 ounces. This patient made an uneventful recovery. A 10-pound child was operated on at the sixth week, then weighing 6 pounds, 4 ounces, a loss of 3 pounds, 12 ounces. This child recovered. An infant weighing 9 pounds, 2 ounces at birth began vomiting at the fourth week. After persistent vomiting for seven weeks he came under my observation. His weight was then 5 pounds, 11 ounces, a loss of 3 pounds, 7 ounces. He died from exhaustion, twenty-six hours after operation. Twelve had made a gain of from 3 ounces to 2 pounds before the onset of vomiting. Two held their birth weight. In the others the birth weight was not looked on as sufficiently accurate to be recorded. Six held or exceeded their birth weight at the time of operation. These patients, of course, had made a pronounced initial gain.

In a collective study of 266 cases by Ibrahim, there were no patients older than 8 weeks at the onset. In one of my patients, vomiting began at birth, eleven were 2 weeks old or under, twelve between 2 and 4 weeks, one was 6 weeks and one 8 weeks.

The onset was abrupt in all but one case.

Twenty-three patients were entirely breast fed at the onset of vomiting, and nine were entirely breast fed when they came under observation. In fourteen the nursing had been discontinued because the breast milk had been thought not to agree. Only two had been bottle-fed since birth.

The vomiting in all was projectile. Twenty-three had vomited after every feeding. In the others there was collective vomiting; two or three feedings were retained and then all vomited. There was no regurgitation or mouthful vomiting. All foods and fluids were vomited alike.

In twenty-four cases there was retention of food three hours or more after every feeding. In two this observation was not made.

The urine and stools were very scanty in all.

There was a steady loss in weight in all the patients after the onset of the vomiting.

There was no elevation of the temperature in any of the cases.

The infants were all very hungry.

The peristaltic stomach wave was present in every case. This is best obtained by washing the stomach and allowing 2 ounces of water to remain, or to give 2 ounces of food. If the patient is given a pacifier and he is then placed on his back with the light favorable for observation, the wave phenomena will shortly appear.

Tumor was palpable in all the cases but one. The tumor may best be palpated when the stomach is empty. In a few cases the tumor will be more readily felt when the stomach contains from 2 to 3 ounces of food. It is most frequently located above and to the right of the umbilicus, and is a small, oblong, movable mass.

In seventeen there was no postoperative vomiting. Nine vomited postoperatively, but all of these recovered. One vomited twenty-two times, and one nine times. Postoperative temperature above 101 was noted in seven. In one it was 104.8, and in one 103. All recovered.

REPORT OF FATAL CASES

Case 1.—An infant, aged 11 weeks, was greatly emaciated, had vomited for ten weeks, and had lost 3 pounds, 7 ounces from the greatest weight, which was 9 pounds, 2 ounces. The child died in collapse twenty-six hours after operation.

Case 2.—A boy, aged 9 weeks, had vomited for two weeks and was in fair condition. I advised immediate operation. This advice was not followed. Other physicians were consulted and he was treated palliatively for three weeks. He was then brought to me in wretched condition, having vomited in all five weeks, and having decreased in weight from 7 pounds, 8 ounces to 6 pounds, 9 ounces. He was operated on and died of exhaustion twenty-four hours after operation.

Case 3.—A boy, aged 7½ weeks, was greatly exhausted before operation, owing to prolonged starvation. He had vomited for four and a half weeks. His greatest weight was 8 pounds, 4 ounces, and his weight at operation 6 pounds, 15 ounces. He died in collapse five hours after operation.

Case 4.—A child, aged 3½ months, had vomited for ten weeks and had decreased in weight from 9 pounds, to 6 pounds, 6 ounces. In spite of prolonged intermittent vomiting, the child was in fairly good condition. I advised immediate operation but was persuaded by the family to take the patient under observation for a few days with a view to avoiding operation. The patient developed an acute gastro-intestinal infection, lost rapidly in weight and vitality, and in three days the operative risk had risen more than 50 per cent. The child died in collapse five hours after operation.

POSTOPERATIVE MANAGEMENT

According to the routine carried out at the Babies' Hospital, which has been evolved under the direction of Dr. L. Emmet Holt and Dr. W. L. Downes, the infant is wrapped in a warm blanket before leaving the operating room, and when in bed is surrounded by hot-water bottles outside the blanket. For an hour or two following operation the head of the bed is kept lowered to prevent the aspiration of mucus into the larynx. This is absolutely necessary while the infant is still under the influence of the anesthetic. When nourishment is commenced, the head of the bed is raised to a level position. Ten or twelve hours later the patient is placed in a semierect position, which tends

---

* Read before the American Pediatric Association, Lenox, Mass., May 28, 1918.

to prevent regurgitation of food and permits the more easy escape of gas.

As soon as the patient is placed in bed, a hypodermoclysis of 120 c.c. of physiologic sodium chlorid solution is given, and if the condition is poor, a hypodermic of 5 minims of epinephrin, 1:1,000, is given and repeated in from four to five hours. Dilute whisky, 5 minims every three hours for the first five or six days, has proved of great value. Transfusion in a few cases of collapse has been of material benefit, from 80 to 120 c.c. of blood from either parent being given, preferably into the median basilic vein.

One and one-half hours after operation, provided the patient has sufficiently recovered from the anesthetic, 10 c.c. of water are given, and one and one-half hours later 4 c.c. of barley water and 4 c.c. of breast milk. Two hours later 8 c.c. of breast milk and 4 c.c. of barley water are given. Breast milk is then given every three hours, alternated with water, and gradually increased in amount so that at the end of forty-eight hours about 30 c.c. are given at a feeding, with 4 c.c. of barley water. The barley water is then discontinued, and on each successive day the amount of milk permitted is increased 5 c.c. at a feeding, so that by the eighth day following operation the patient is having 60 c.c. every three hours. On the third day the intervals of feeding at night are lengthened to four hours, so that seven feedings are given instead of eight. By the time the baby is taking 60 c.c. of breast milk at each feeding he may be put to the breast once. The baby is weighed before the nursing and at intervals of three minutes until he has nursed 60 c.c. from the breast. The following day three nursings are allowed, so that by the eleventh or twelfth day the patient is nursing entirely and is able to leave the hospital. Measurement of food during the nursing must be kept up one week later by carefully weighing both before and after. For one month or longer a wetnurse is advisable if the mother is not able to nurse her child.

In well-nourished infants, a sponge bath is given daily until the wound is completely healed. In emaciated children, an oil rub is preferable until such time as the tendency to subnormal temperature has passed.

In cases of vomiting due to accumulation of gas in the stomach, the child should be raised to an upright position after feeding. If this does not suffice, a soft rubber catheter may be passed into the stomach before each feeding. If still persistent, gastric lavage may be employed. One teaspoonful of castor oil is usually given twenty-four hours after operation if there have been no stools. There should be from two to three stools a day. If they are more frequent, protein milk is substituted for three or four breast feedings.

The wound is covered with a narrow fold of sterile gauze held in place by adhesive straps. It is not disturbed for four or five days unless some indication arises. The stitches are removed on the ninth or tenth day.

MORTALITY

A low mortality in these cases of pyloric stenosis depends on early diagnosis and immediate operation. The presence of a palpable tumor demands prompt surgical interference. The longer operation is delayed in a case with a well-marked tumor the greater the surgical risk. This does not mean that a child with a palpable tumor cannot recover without operation. I have had patients with palpable tumor recover and others that died without operation and after operation because of operative delay. Operation by the Rammstedt method (which means a rapid operation) will insure a mortality of about 5 per cent. in patients that have not vomited more than two weeks. The surgical risk that the patient offers depends in large measure on the duration of the vomiting. It is assumed, of course, that adequate after-care, which includes the use of breast milk, is supplied.

It will be observed that my four patients who died had vomited from four and a half to ten weeks.

A false security in these cases is assumed from the fact that the loss in weight is often temporarily arrested or perhaps has not been excessive. The cases reported above represent those in which operation was performed during the past four years and not all those that have come under observation, nor do they include those patients operated on or otherwise treated previous to 1914, when the results were not so brilliant. Cases treated by nonoperative methods will form the topic of a later communication. Sudden and unexpected death in the palliatively treated cases of pyloric stenosis is not uncommon. Acidosis,[1] due to defective urinary secretion with retention of acids, may explain these sudden deaths.

CHRONIC PERICHOLECYSTITIS WITH MARKED GASTRIC SYMPTOMS

JOHN W. CHURCHMAN, M.D.
NEW HAVEN, CONN.

The fact that inflammatory affections of the gallbladder, and stones in the gallbladder, are associated with gastric symptoms is sufficiently appreciated; but a series of cases recently seen in the New Haven Hospital has led me to doubt whether the association of marked and almost exclusively gastric symptoms due to inflammatory conditions about the gallbladder (with resultant adhesions in its neighborhood) has been sufficiently well recognized.

The complaints of the five patients here reported were almost entirely referred to the stomach, and they were of so severe a degree as to cause insistence in every case on operative intervention. In every case the freeing of the adhesions in the neighborhood of the gallbladder, and cholecystectomy, have resulted in prompt and complete relief.

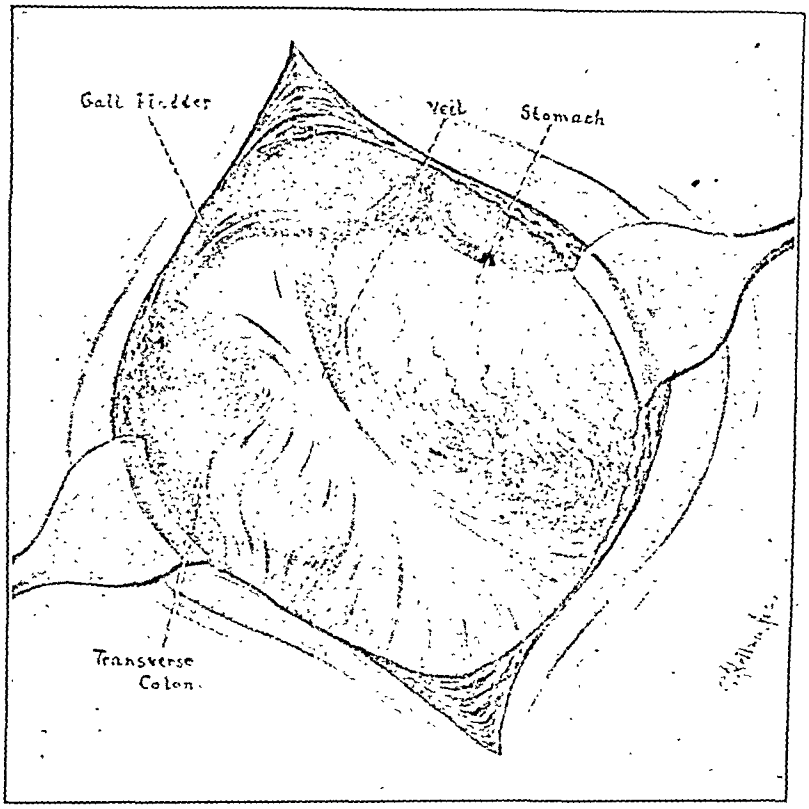
It is certainly true that much has been said and written concerning abdominal adhesions that is not justified by wide experience in surgery for one often meets well marked adhesions in the abdomen that have caused no symptoms whatever, and on the other hand moderate adhesions that are so placed as to be responsible for a good deal of discomfort or suffering.

The type of adhesion which I have in mind in this paper and which was present in all the cases reported was not the light, veillike structure often encountered, but a thick, firm, extensive adhesion of the gallbladder to the stomach, to the liver, to the transverse colon and to the abdominal wall. Whether these adhesions represent a previous cholecystitis with stones, the stones having been meanwhile discharged, it is impossible to say. A study of the onset as given in the histories does not indicate that this is always the case. In Case 1, for example, there had been no attack to suggest gallstones in the gallbladder at any time. Gradually, the only symptom complained of ("feeling as though there were a lump in the stomach") made its appearance and persisted for a year and a half. In Case 3 there had been for three years a dull, gnawing pain in the pit of the stomach. This pain suggested rather the pain of an ulcer and was relieved by eating; but at operation no sign of ulcer was found, though it is true that the cystic duct was adherent to the surrounding tissues. In Case 5, the pain had been unusually severe, usually localized in the epigastrium but occasionally radiating to the back and shoulder. In a word, the character of the pain varied from a gastric distress to the pain characteristic of ulcer or of stone in the gallbladder, but at the time of operation neither of these conditions was found, except that in Case 2 the gallbladder contained one large stone. In this case the intensive adhesion of the gallbladder to the transverse colon was such a marked feature that I have included it in the series, though it is possible that the case was simply one of cholelithiasis, and that the adhesions had little to do with the clinical picture.

---

[1] Schloss, O. M.: Intestinal Intoxication in Infants, Am. J. Dis. Child. **15**:165 (March) 1918.

The importance of this class of cases consists in impressing on us that in patients in whom clinical examination does not reveal signs of gastric ulcer and in whom the physical examination for gallstones is negative, a clinical picture of pain in the upper quadrant or in the stomach region associated with eructations of gas may be entirely due to a marked inflammation about the gallbladder leading to its adhesion to surrounding viscera. It is interesting to notice that in one of the cases, Case 4, blood was found in gastric contents by the benzidin test. In all these cases a cholecystectomy gave prompt and complete relief, and this, of course, is the operation that should be done. Indeed, if this clinical picture represents the late results of a previous cholelithiasis, it is another argument for doing a cholecystectomy when gallstones are found in the gallbladder, and this is the operation which should, I believe, always be done. It is an operation that is much more difficult to do after a gallbladder has been drained, as I have recently had occasion to experience, having performed a cholecystectomy on a patient on whom a cholecystostomy for gallstones had been done some years previously. In this patient the gallbladder was tightly adherent to the pylorus and by these adhesions had been drawn backward toward the posterior peritoneal wall so that it had to be very carefully dissected away from the neighborhood of the vena cava, and in cutting its cystic duct the greatest possible care had to be used so as not to injure the common duct. This is a point to which recent writers have called frequent attention, but it is a point that cannot be too much stressed in discussing cholecystectomy. There is no excuse for injury of the common duct in dividing the cystic duct, if the cystic duct is thoroughly freed before it is clamped. If this is not done, however, the variations in the anatomic relations of the cystic and common duct, and the changes in its position due to adhesions, will frequently lead to inclusion of the common duct in the clamp which grasps the cystic duct and therefore to injury of the former.



Veil of firm adhesions found in Case 1.

I do not think it can be said that the clinical symptoms associated with adhesive pericholecystitis are characteristic enough to make us sure of a diagnosis of adhesions about the gallbladder. The study of these cases does not reveal any characteristic symptom or syndrome, but it becomes increasingly evident that symptoms referable to the right upper quadrant should, in all cases in which positive diagnosis cannot be established, lead to an exploration; for, aside from the well-known fact that both cholelithiasis and gastric ulcer may be overlooked if routine explorations of this kind are not made, it is also true that cases of the sort here reported, which in their milder form might well be classed as gastric neurasthenia, would go unrelieved unless explored and the adherent gallbladder excised. No results could be more gratifying than the complete relief afforded these wretched patients.

REPORT OF CASES

Case 1.—*History.*—M. A., woman, aged 40, for about one year had had a feeling "as though there were a lump in the stomach." There had been no actual pain, but the distress from the lump had been present constantly and had made life almost unendurable, so much so that she insisted on operative exploration. There had been no evidence of gastric obstruction, though she had noticed that she vomited whenever tea or coffee was taken with the meals. When these were omitted there was no vomiting. The previous history was unimportant.

Gastric analysis revealed: fasting contents, 30 c.c.; free acid, 40; total acid, 60; microscopic and benzidin, negative. Test meal, 100 c.c.; free acid, 20; total acid, 60; microscopic and benzidin, negative.

The symptom as to the lump in the stomach, which was the *only feature of the disease, was not* connected with any cause which the patient could determine, and bore no relation to food or to hunger. It was associated with nausea, but there was no vomiting. The symptoms were worst in the morning, and the patient never had any appetite for breakfast. She was a nervous woman, but there was no hypertrophy of the thyroid or sign of exophthalmic goiter.

The roentgen-ray examination threw no definite light on the case. An exploration was advised, but no assurance could be given that relief would be obtained.

Operation and Result.—When the peritoneal cavity was opened, a sheet of strong adhesions extending from the under surface of the right lobe of the liver spread downward in fan-shaped fashion, enveloping the gallbladder, to the stomach, transverse colon and hepatic flexure, and backward, encroaching on the foramen of Winslow. The gallbladder was slightly larger than normal but otherwise unchanged, and contained no stones. The appearance of the veil is shown in the accompanying illustration. The veil was divided so as to free all the viscera involved and the gallbladder was dissected free and removed.

There was complete relief of symptoms, and the patient left the hospital cured, able to eat well, and entirely free from distress.

Case 2.—*History.*—D. B., woman, aged 43, for three weeks had complained of severe pain in the stomach with eructations of gas. The pain was not related to meals and was constant. It was dull and gnawing in character and had made life so miserable that operation was insisted on. There was no jaundice nor history of jaundice. The abdominal examination revealed some tenderness in the region of the gallbladder and just under the left costal margin. The patient would not relax the rectus muscle, and examination was difficult; but it was my impression that a mass was felt in the region of the gallbladder.

Roentgen-ray examination indicated a probable ulcer of the first portion of the duodenum; marked adhesions in the terminal pyloric portion with partial obstruction of the duodenum, and cecal adhesions.

Operation and Result.—The gallbladder was thickened, somewhat enlarged, adherent to the transverse colon, and pulled well over to the right side by adhesions. It contained one large stone. The appendix was surrounded by adhesions. Cholecystectomy and appendectomy were performed.

The convalescence was somewhat prolonged by a mild infection of the operative wound, but relief from symptoms was complete.

Case 3.—*History.*—S. S., man, aged 34, for three years had complained of a dull gnawing in the pit of the stomach. This was relieved by eating, but returned an hour and a half after food was taken. There was occasional nausea, but there had been no vomiting. There had been a good deal of gaseous eructations. There was no jaundice. The patient had lost about 15 pounds in weight and had become less vigorous and energetic. The family and previous history was unimportant. The typical hunger pain with brief relief on the taking of food was to be especially noticed. Abdominal examination was negative except for tenderness in McBurney's region. The roentgenologic findings indicated adhesions in the regions of the terminal pylorus, interfering with the emptyings of the stomach.

Operation and Result.—The gallbladder was adherent to the stomach and the cystic duct to the tissues around it by fresh adhesions. There were no stones nor ulcers. The appendix was long, thick, and slightly reddened. Cholecystectomy and appendectomy were performed.

The relief from the operation was prompt and complete, and the patient left the hospital entirely cured and eating in normal fashion.

Case 4.—*History.*—L. M., man, aged 66, for two months had complained of pain in the epigastrium which came on one hour after eating and lasted for two or three hours. The pain was relieved by drinking hot milk. He did not vomit. There had been no tarry stools, but he had lost 20 pounds in two months. Two years before he had a similar attack which lasted one month.

Abdominal examination revealed tenderness and resistance in the epigastrium, beginning under the left costal margin and running to about the middle of the right rectus muscle.

Gastric analysis revealed blood microscopically by the benzidin test. In examination of the fasting contents, 30 c.c. were obtained, with a total acidity of 42. Free hydrochloric acid was 22. In a test meal, 120 c.c. were obtained, with a total acidity of 65, and free hydrochloric acid, 30.

Roentgen-ray examination indicated a growth in the pyloric portion outside the stomach proper, producing pressure on the pylorus, and a diagnosis was made by Dr. Honeij of marked adhesions in that region also involving the hepatic flexure and transverse colon.

Operation and Result.—The gallbladder was densely adherent to the liver, hepatic flexure, transverse colon and duodenum. There were no stones in the gallbladder. The appendix was quite long and covered with adhesions, its tip lightly adherent to the under surface of the liver. Cholecystectomy and appendectomy were performed.

The severe gastric symptoms which before operation had made life miserable were entirely relieved, and the patient left the hospital a normal man.

Case 5.—*History.*—M. M., woman, aged 49, for seven months had had severe pain in the epigastrium, part of the time localized to this region, part of the time radiating to the back and shoulder. She had vomited occasionally, never any blood. There had been no jaundice. She had lost 20 pounds in three months, and had been greatly troubled by gaseous eructations and by nearly constant nausea. There had been no relation between the pain and the taking of food.

Operation and Result.—At operation a general visceroptosis was found, excluding the kidneys; but the chief lesion consisted in firm adhesions of the gallbladder to the duodenum, of the stomach to the colon, of the parietal peritoneum to the ileum. The stomach and duodenum were carefully explored for ulcers and none found. There were no stones in the gallbladder. The gallbladder and the appendix, possibly previously inflamed, though at present showing no changes, were removed.

The symptoms were entirely relieved by the operation, and the patient left the hospital feeling perfectly well and eating normally.

GAUCHER TYPE OF SPLENOMEGALY

REPORT OF A CASE

JAMES G. CARR, A.B., M.D.
Assistant Professor of Medicine, Northwestern University Medical School; Attending Physician, Cook County and Mercy Hospitals

AND

LOUIS D. MOORHEAD, S.M., M.D.
Resident Physician, Cook County Hospital

CHICAGO

Among the numerous conditions that are included under the general term of Banti's disease, there is one group of cases with definite clinical and pathologic characteristics. We refer to that known as the Gaucher type, first described by Gaucher in 1882. Brill and Mandlebaum,[1] in an exhaustive study, say:

> The characteristic features of Gaucher's disease are its incidence in childhood, its frequent presence in other members of the family of the same generation, a progressive increase in the size of the spleen, which often reaches colossal dimensions, followed by a similar huge enlargement of the liver, a characteristic brownish-yellow discoloration of the skin, usually restricted to the face, neck and hands, a peculiar yellowish, wedge-shaped thickening of the conjunctiva, commonly seen on both sides of the cornea, and the prolonged and chronic course of the disease, which does not materially disturb the health of the individual. After the disease has been present for a considerable time, there is a definite tendency to hemorrhages, especially appearing as epistaxis, bleeding from the gums, and ecchymoses in the skin following the slightest trauma. The positive finding in the blood, even in the early stage of the disease, is a definite leukopenia. The erythrocytes, however, show no definite change either in number, form, size or hemoglobin content until the disease has existed for a long time, when an anemia of the chlorotic type makes its appearance. The anemia is rarely pronounced at any stage. The disease is not accompanied by palpable enlargement of the superficial lymph nodes. There is no

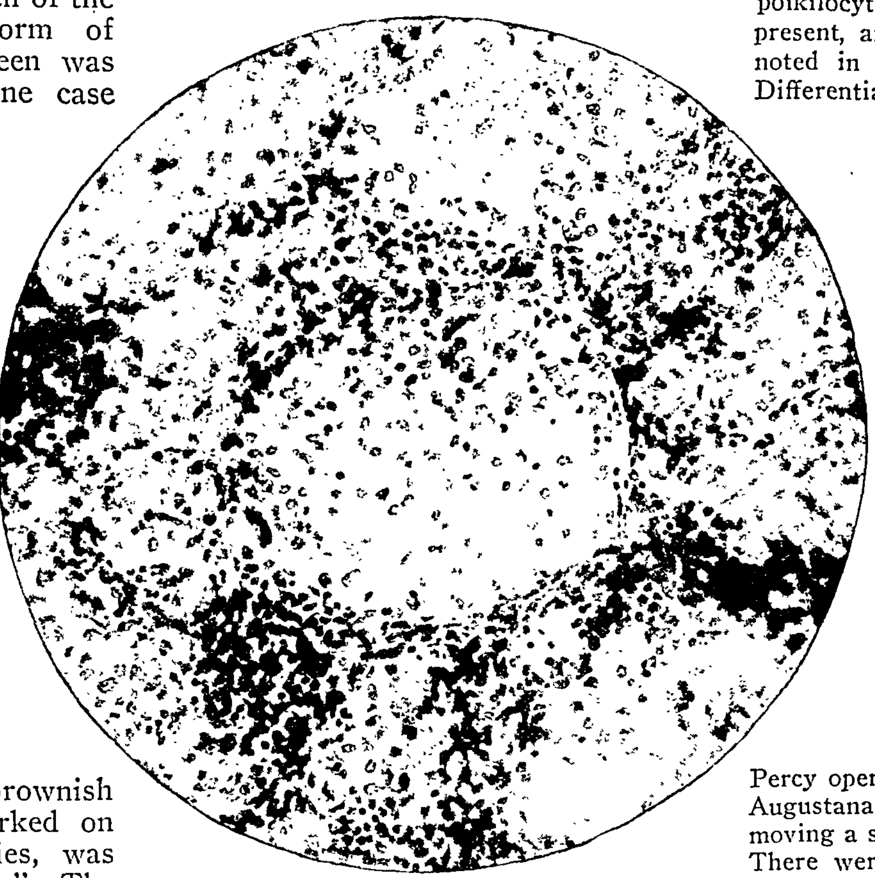
---

[1] Brill, N. E., and Mandlebaum, F. S.: Am. J. Med. Sc. **146**:863, 1913.

jaundice, and ascites is exceptional. The disease has none of the characteristics of malignancy, and usually is terminated by some intercurrent affection.

The pathological feature of the disease is the presence in the spleen, liver, lymph nodes and bone marrow of distinctive large cells, with characteristic cytoplasm and small nuclei. The enlargement of the spleen and liver is due to the presence of these cells in enormous number. In well-established cases, all of these organs contain pigment giving the reaction for iron. Whereas the nature and origin of these cells are still moot questions, the histological picture is uniformly characteristic and pertains to no other form of disease.

In 1916, Knox, Wahl and Schmeisser[2] reported two cases, and collected all of the instances recorded to that time, sixteen in number; the oldest patient was 44 years of age; only three of the patients were males. "The onset of the disease is insidious, the symptoms being vague and indefinite. A feeling of weight accompanying the enlargement of the abdomen was usually present." Eleven of the patients had some form of hemorrhages. The spleen was greatly enlarged, in one case weighing 8,100 gm. "Enlargement of the liver was noted in fourteen cases. It was not so marked as that of the spleen and seemed to occur at a somewhat later period. . . . The superficial lymph glands were moderately enlarged in ten instances, and in three additional cases, certain internal groups of lymph glands were enlarged." In one of the cases reported by these authors, the diagnosis was confirmed during life by the examination of an excised lymph node. "A yellowish or brownish discoloration, most marked on the face and extremities, was noted in eleven cases." The importance in diagnosis of the "wedge-shaped thickening of the conjunctiva," mentioned by Brill and Mandlebaum, has not been determined in the opinion of Knox, Wahl and Schmeisser. The blood picture, the familial history and the final termination are as stated by Brill and Mandlebaum. In one case, a white cell count of 500 was noted. Splenectomy was performed in nine cases. "Three of the patients died shortly after the operation. Only one was reported living after sixteen months. In most of these the sense of *weight in the* abdomen had been relieved, but there is no evidence that the further progress of the disease was arrested."



Section of spleen, × 200, in Gaucher type of splenomegaly, with large irregular spaces, representing the greatly dilated venous sinuses, filled with the peculiar large cells and nuclei relatively small, sometimes single and sometimes multiple.

REPORT OF CASE

P. W., man, aged 46 years, Polish, an insurance solicitor, unmarried, who first entered Cook County Hospital in November, 1915, had known since childhood of a tumor in the side of the abdomen. Attention was first directed to when he was 9 years of age. The tumor gradually increased in size, though the patient's general health was always good. The tumor produced neither pain nor tenderness, but at the time of entrance to the hospital, the patient was suffering from difficulty of respiration, which was sufficiently severe to prevent the discharge of his daily work.

The patient was very emaciated, and yellowish looking. Examination was generally negative except so far as it concerned the emaciation, the abdominal findings and the blood. There was no general adenopathy. The heart was normal except for a soft systolic blowing murmur, heard at the base. The abdominal tumor was determined to be the spleen. It extended to within 5 cm. of the symphysis pubis, and beyond the median line to 5 cm. to the right of the umbilicus. It was hard, smooth and not tender. The liver was palpable 10 cm. below the costal arch. The lower extremities were moderately swollen. Blood examination revealed: hemoglobin, 35 per cent.; erythrocytes, 2,240,000; leukocytes 3,200. A second count was practically the same, the leukocytes, however, being only 2,100. There was no increased fragility of the red cells; poikilocytes and microcytes were present, and three normoblasts were noted in one of two examinations. Differential white count revealed: small mononuclears, 17; large mononuclears, 12; polymorphonuclears, 68; eosinophils, 1; transitionals, 1; myelocytes, 1.

There was no history of previous illness, other than this one. Venereal disease was denied. Family history was negative. Coffee and tobacco were used to excess. Alcohol was used in moderation. The Wassermann test was negative. The diagnosis of Banti's disease was made, and the case was regarded as probably of the Gaucher type. Operation was suggested but refused, and the patient left the hospital.

In May, 1916, Dr. N. M. Percy operated on the patient at the Augustana Hospital, Chicago, removing a spleen 11 pounds in weight. There were firm adhesions between the upper pole and under surface of the diaphragm. The liver showed a fatty and atrophic cirrhosis. Transfusion was done, 600 c.c. each time, before the operation and on the day following. On the day after the operation the blood count revealed: hemoglobin, 70 per cent.; erythrocytes, 6,150,000; leukocytes, 2,900; differential white count: polymorphonuclears, 86, no abnormal red cells. Four days later, the hemoglobin was 70 per cent.; erythrocytes, 5,350,000; leukocytes, 1,920. On section the spleen showed large irregular alveolar spaces, representing the greatly dilated venous sinuses, filled with the peculiar large cells with nuclei relatively small, some*times single*, sometimes multiple, characteristic of the Gaucher type of splenomegaly. An iron-containing pigment was found between the connective tissue fibers of the trabeculae. The patient made an uneventful recovery and left the hospital in three weeks.

Jan he patient again entered Cook County Hospital,
and or six months he had been losing weight.
g nocturnal headaches; swelling and sore-
ıad been present for six weeks; bleeding
n as an oozing two weeks before admis-
stead orse. Some of the teeth were

---

[2] Knox, Wahl and Schmeisser: Bull. Johns Hopkins Hosp. 1916.

loosened and the breath was fetid. The history was suggestive of insufficient nourishment. The blood test revealed: hemoglobin, 85 per cent.; erythrocytes, 3,950,000; leukocytes, 9,000; differential white count: small mononuclears, 28; large mononuclears, 13; polymorphonuclears, 54; eosinophils, 2; transitionals, 3. Erythrocytes were normal in appearance. On an antiscorbutic diet, the patient improved rapidly and was discharged, March 3, 1918, feeling well. All of the abnormal physical findings recorded at the time of entrance had disappeared. Repeated white counts made during his stay in the hospital revealed from 8,600 to 9,200 leukocytes. On the day of his discharge, the blood test revealed: hemoglobin, 90 per cent.; erythrocytes, 4,750,000; leukocytes, 8,600; differential white count: small mononuclears, 27; large mononuclears, 11; polymorphonuclears, 61; transitionals, 1.

SUMMARY

1. This case presented the clinical features regarded as characteristic of Gaucher's type of splenomegaly.
2. No case in which the patient was as old as this *man has as yet been reported.*
3. The patient was seen twenty-one months after splenectomy (the longest time elapsing since operation yet reported), and the blood findings were approximately normal.
4. There was no diminution in the size of the liver as a result of the operation.

A CASE OF CONGENITAL RADIO-ULNAR SYNOSTEOSIS

JONAS C. KOPELOWITZ, M.D. (ST. LOUIS)
First Lieutenant, M. C., U. S. Army
NEWPORT NEWS, VA.

Congenital synostosis of the upper ends of the radius and ulna is a rather rare condition. In this deformity there is an osseous fusion of the upper ends of these bones. Feidt[1] has reported two cases occurring in mother and daughter, and Kurlander[2] has reported a case of unilateral radio-ulnar synosteosis in an 8-year-old boy who gave no hereditary history. These are the only cases reported in American literature, and Feidt has collected about forty instances in the entire literature. Most of the cases showed a strong tendency to follow certain laws of heredity. This was present in Feidt's cases, mother and daughter being affected, with a history of the condition in the grandfather.

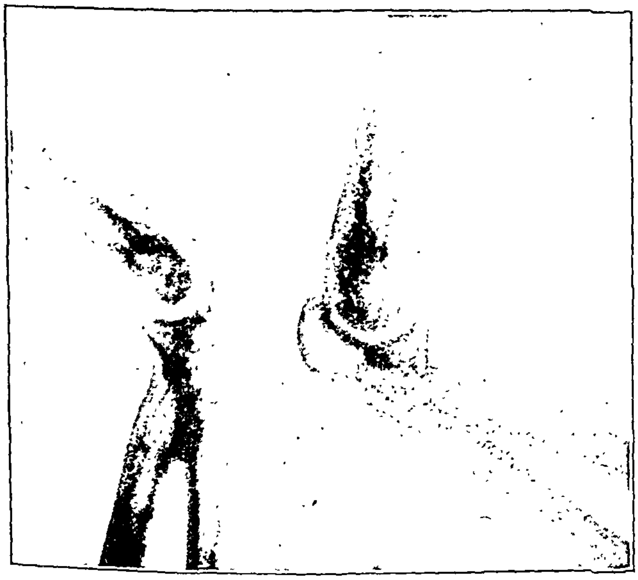


Fig. 1.—Synosteosis: lateral view.

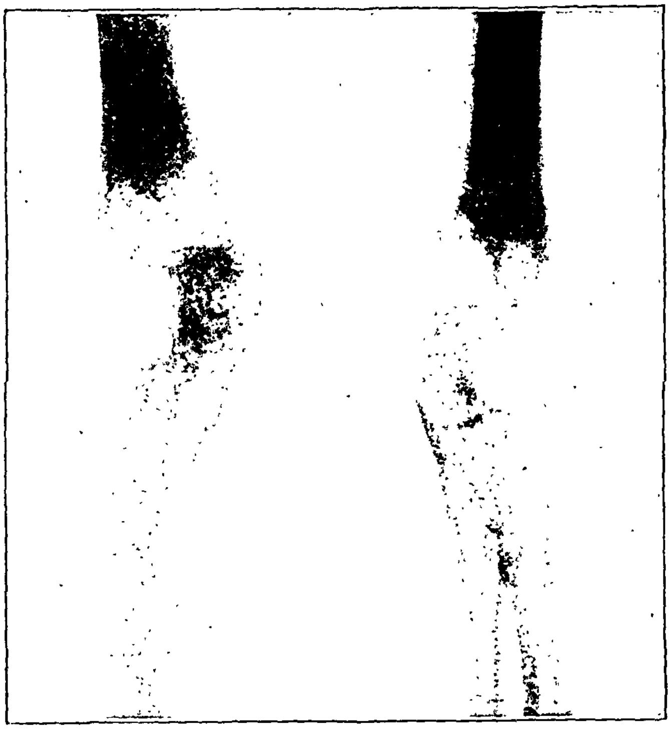

Fig. 2.—Synosteosis: anteroposterior view.

In this deformity the function of supination of the forearm is lost. There is no satisfactory treatment. In a case reported by Dawson,[3] the patient was operated on five times with fairly good results, with a restoration of the function of supination.

The case that I report is identical in its features with those reported by Feidt. There was no hereditary tendency discovered in my case.

REPORT OF CASE

A man, aged 22, colored, a native of Louisiana, seen at the Embarkation Hospital, Newport News, Va., had been a hotel porter previous to his induction into military service. He had never been able to rotate his forearms. Both hands were held in semipronation. Flexion at the elbows was normal; extension was not quite maximal. The wrist movements were normal. There was inability to supinate the forearms, any attempt at supination bringing into action the muscles of the arm and shoulder. Incidentally this patient presented a chronic arthritis of the left knee with a positive Wassermann reaction. The roentgenograms of both forearms, taken by Lieut. Ralph H. Boice, show intimate bony union of the upper 6 centimeters of the radius and ulna, both forearms showing identical involvement. The patient was discharged from the Army.

Indications for Transfusion.—The most reliable index of the need for transfusion in those suffering from acute anemia is the persistently lowered systolic blood pressure *true whether there has been actual hemorrh* there exists the capillary stasis (potential anemia) peculiar to shock.—*Review of Medicine.*

Clinical Notes, Suggestions, and New Instruments

A CASE OF ACUTE METHYL SALICYLATE POISONING

Jacob Rosenbloom, M.D., Ph.D., and James R. Johnston, M.D., Pittsburgh

A search of the literature reveals that cases of poisoning by methyl salicylate are very rare. Nerthney[1] reported a fatal case of poisoning. Juvet[2] described a case resulting fatally after the taking of one-half ounce of oil of wintergreen, and Gallaher[3] reported a case with recovery following ingestion of the same amount of oil of wintergreen. Pinkham[4] reported a case in which the patient died in fifteen hours after taking 1 ounce of oil of wintergreen as an abortifacient. It produced sweating, abdominal pain, purging, frequent and painful urination, convulsions, loss of sight and hearing, and death in coma. Necropsy disclosed the presence of gastritis and congestion of the kidneys. Hamilton[5] reported a case with recovery following ingestion of one-half ounce of the oil. The patient was dizzy, drowsy, delirious, went into coma, and developed a hemiparesis and salivation and a permanent disturbance of vision. Mann and Brend[6] report a case in which 3 drams of the oil killed a boy, aged 3 years, with convulsions as the most marked symptoms.

REPORT OF CASE

Miss B., aged 40, schoolteacher, at 9:30 p. m., March 28, 1918, took 1 ounce of oil of wintergreen, thinking that it was liquid petrolatum. Twenty minutes later she went to bed. Immediately after lying down she experienced a burning sensation in the abdomen and extreme nausea. She vomited, and the vomitus consisted of oil of wintergreen. Immediately following the vomiting diarrhea occurred, and the stools burned in passage. She washed her stomach by drinking water and took a glass of milk. The vomiting and diarrhea continued.

About half an hour after she had taken the oil, tinnitus aurium began. She felt that she needed air, and went to the front porch. She was examined two and one-half hours after taking the oil. The pulse was 120 and weak. There was a marked odor of oil of wintergreen throughout the house.

Castor oil, 2 ounces, liquid petrolatum, 1 ounce, and olive oil, 1 ounce, were given every second hour. Proctocysis was done with glucose, 10 per cent., and sodium bicarbonate, 5 per cent.

The following day the pulse was 110 and weak. The systolic blood pressure was 100, the diastolic not obtainable. The urine, 20 ounces, contained a heavy ring of albumin and a few hyaline and granular casts, and gave a strong salicylate reaction with ferric chlorid. The patient had extreme nausea, and vomited repeatedly. She had a sensation of things being far away. The tinnitus still persisted. She was given 1 pint of salt solution by hypodermoclysis in addition to the previous treatment instituted.

The third day the pulse was 80 and weak. The extreme nausea and vomiting continued. The temperature and respiration were normal.

The fourth day the temperature was 101.5, the pulse 80 and the systolic blood pressure 120. The patient was restless, excited and very nervous. The nausea and vomiting continued. Twelve ounces of blood were withdrawn and 1 pint of salt solution given intravenously. The treatment was continued with the addition of cocain, one-sixth grain by mouth, before food, and an alkaline drink was given by mouth.

The fifth day the temperature was 100 and the pulse 80. Nausea and vomiting were still present. A bad taste was present in the mouth. The urine volume was 900 c.c., with one part of albumin to the liter. Acetone and diacetic acid were present in large amounts. Salicylate was present in the urine.

The sixth day the nausea and vomiting had stopped. The temperature was 99.4 and the pulse 80. All food tasted sweet. The urine volume was 520 c.c. with one-fourth part albumin to the liter. Acetone and diacetic acid were present in large quantities. Salicylate was absent.

The seventh day the temperature was normal and the patient's condition normal except for fatigue and a sensation of her head falling into space. She had to wash her mouth constantly to keep soap bubbles out that would form. The urine showed 1.3 parts of albumin to the liter, and gave positive reactions for acetone and diacetic acid. Salicylate was absent. From this time on the patient's condition was normal. The acetone and diacetic acid disappeared on the twelfth day of her illness and the albumin on the seventeenth day.

TREATMENT OF A SEVERE CASE OF EPIDEMIC MENINGITIS BY COMBINED INTRAVENOUS AND INTRASPINAL INJECTIONS OF ANTIMENINGOCOCCUS SERUM

Archibald L. Hoyne, M.D., Harry S. Arkin, M.D., and M. J. Sherman, M.D., Chicago
Attending Physician and Resident Physicians, Respectively, Cook County Hospital

We report this case because of the rapidity with which the symptoms cleared up under the combined method of treatment:

Harry T., aged 18, entered the Cook County Hospital, Aug. 25, 1918, in a state of delirium, with the history that, forty-eight hours previously, he had developed a severe headache followed by projectile vomiting and fever, and had been irrational for twenty-four hours.

Physical examination revealed marked rigidity of the neck with retraction of the head, opisthotonos, eyes deviating to the right, all reflexes exaggerated, positive Kernig and Brudzinski signs, rectal temperature 102.8, and pulse, 90. He was very restless and delirious, and it required several assistants plus partial ether anesthesia to do a spinal puncture. The fluid, 30 c.c. of which was withdrawn, was highly turbid, under increased pressure, with a cell count of 21,200 per cubic millimeter. Smears showed numerous intracellular and extracellular gram-negative diplococci. Ross-Jones and Nonne globulin tests were positive. Thirty c.c. of serum were given intraspinally.

On the following day the patient's condition showed no improvement. Forty-five c.c. of spinal fluid were withdrawn. The fluid was still very turbid with a cell count of 16,400 per cubic millimeter. Thirty c.c. of serum were given intraspinally and 45 c.c. intravenously.

Twenty-four hours later the temperature had fallen to 100 and the general condition was somewhat improved. Thirty-five c.c. of spinal fluid, less turbid than before, were obtained by puncture, and the cell count was now 1,000 per cubic millimeter. Twenty c.c. of serum were given intraspinally and 70 c.c. intravenously.

On the fourth day his condition was much improved. The spinal fluid (30 c.c. were withdrawn) was only faintly turbid with slight increase of pressure, and cell count of 450 per cubic millimeter. Fifteen c.c. of serum were given intraspinally.

On the following day—the sixth day from onset—spinal puncture revealed a clear fluid with a cell count of only 60 per cubic millimeter. Smears showed no organisms.

No further injections of serum were made, and on September 7, fifteen days after entering the hospital, the patient was discharged with complete recovery.

The total amount of serum given was 115 c.c. intravenously and 95 c.c. intraspinally.

There was no reaction following any of the intravenous injections of serum. This may be attributed to the fact that the patient had already been sensitized by the first intraspinal injection, which was given twenty-four hours before the administration of the serum by the intravenous method, and the fact that the first few cubic centimeters were injected very slowly.

[6] Mann and Brend: Forensic Medicine and Toxicology, 1914, p. 685.

Another point to be emphasized is the great need of judgment in determining the amount of serum to give intraspinally. We believe it imperative to drain the spinal canal as frequently as the case demands, but not to give serum on each occasion a puncture is made. Through irritation of the meninges by superfluous serum a turbid fluid with high cell count may result. We feel there is no doubt that in many instances the clinical symptoms of epidemic meningitis are prolonged by the continual injection of serum intraspinally far in excess of the amount required to obtain a cure.

OBSCURE INFLAMMATIONS OF THE CAUDA EQUINA: REPORT OF CASE AND OPERATION

Cecil E. Reynolds, M.D., D.P.H., Los Angeles

In 1914, Kennedy, Elsberg and Lambert[1] reported five cases of a peculiar undescribed disease of the nerves of the cauda equina. In this series they demonstrated not only the great benefit to be derived from operation, but also much of the pathology of the disease.

As I have had occasion to operate recently in a case that closely resembled Case 4 in the foregoing series, an account of it may add something to the study of the subject.

REPORT OF CASE

History.—A. G. R., man, aged 48, until five years before I saw him lived in Mexico. His father and sister died of tuberculosis. He had never had any serious illness except "stomach trouble" five years before, which lasted about a month, and the backache which preceded his present illness. This backache appeared eight years before. The first attack lasted two months, but on removing from Guadalajara to Vera Cruz he was immune for a year. At the end of that time he came to Los Angeles, and the backache returned in attacks every month until October, 1917, when the pain became continuous and was now associated with a sensation of numbness over the front of the right thigh. In March, 1918, after one remission, the numbness extended to the right ankle and sole of the foot, and there was a painful weakness of the arch when walking. March 10, he noticed numbness on the inner side of the left shin. Until March 10 he had been able to work and walk without a stick, but, after a series of osteopathic manipulations, which at times were very painful, he developed a sensation of a tight band around both Poupart's ligaments, and also around the knee and ankle on the right side. He used a stick until April 1, when he was compelled to stop work, and on May 1 collapsed entirely and had to be carried.

Examination.—Dr. Alfred Fellows saw him, May 5, and called me in, May 6. The patient was pale, thin, sallow and nervous in appearance. He was seated in an easy chair, but could not raise either foot from the ground. He could raise the right heel slightly. There was an almost complete flaccid paralysis of both lower limbs. Marked foot-drop had evidently existed for quite a while on the right side, as complete passive dorsiflexion was impossible beyond a right angle. There was complete absence of both knee jerks and also of both plantar reflexes. The feet were swollen, purplish and cold, especially the right foot. There was considerable atrophy of the muscles of both legs and both thighs. There was anesthesia over the dorsum of the right ankle and right sole, but elsewhere very little alteration of sensation except a marked saddle anesthesia (above) on both sides of the anus and inner aspects of the buttocks and to a lesser extent of the scrotum. There was no dissociation. Areas of hyperesthesia were noted on the right leg and foot. The abdominal reflexes were present; the cremasteric reflexes were slight. The bulbocavernosus reflex was absent. Above the waist line there were no special physical signs.

At this examination the patient complained of severe and continuous pains in the lumbar region and down the right leg (the outer side especially) and less severe in the left leg. Also there had been difficulty of micturition for the past two weeks, and constipation for years. Cramps in the legs and "electric shocks" were also complained of in the legs. He denied syphilis. The Wassermann test was negative, both as to blood and spinal fluid.

May 8, there was complete retention of urine.

Operation and Result.—May 9, operation was performed in the California Hospital. The roentgenograms being quite negative, I removed the arches of the eleventh and twelfth dorsal and first and second lumbar vertebrae. The epidural fat was very scant. On exposure, the dura mater was seen to be dark and swollen and to have spontaneously ruptured. A vertical slit was present through which the congested cauda endeavored to extrude. A light tampon was placed above the swelling between the dura and the bone, and the dura freely opened. The dura was smooth on its inner aspect.

The following condition was found: The posterior roots on the left side appeared nearly normal, but those of the right side were inextricably imbedded in a purplish mass of what seemed to be inflammatory material, molding itself into a smooth tumor-like substance closely applied to the lateral wall of the spinal canal as one traced it forward as far as possible without causing further trauma to the nerve tissues. It extended all the way around to the front of the right cauda, and I have no doubt from the symptoms that it also involved the left anterior roots; but it seemed so probable that an attempt to unravel the adhesions in that confused mass might forever damage the bladder mechanism, and thus abolish the chances of natural resolution that I decided to search no farther for the boundaries of the mass or even for the conus above it, and contented myself with thorough irrigation with mercuric chlorid 1 : 1,000, and as it was impossible to close the dura, I stitched the muscles carefully together over the cauda after removing the tampon. Very little cerebrospinal fluid escaped. The dura was left wide open to insure full decompression. A little fluid escaped next day, but none thereafter.

Immediate relief from pain followed the operation and has continued to the present. The bladder acted normally for a week after operation, when the patient had an attack of acute retention, and required catheterization for two weeks, since which time he has passed urine normally. The muscular power has steadily increased so that now he can walk well with one stick, and up and down stairs. He contemplates returning to work next month. Slight saddle anesthesia is still present. Both knee jerks are present, the left more than the right. The left plantar reflex is present, the right absent. The left leg is carried normally in walking, but the right is rather high-stepping. Right foot-drop is still present. The left ankle movements are strong in all directions. Both thighs can be powerfully flexed on the abdomen. The heel and toe pointing test is good, but better on the left. Sensation everywhere is normal, even on the right foot, excepting only the slight saddle hypesthesia and a very slight band sensation in the region of the right knee. Swelling and blueness of the feet have disappeared. Sexual desire and the power of erection have returned. Both legs are considerably more muscular, and the patient has gained in weight and improved in color. His tongue has still the thick coat of gray fur that it has carried for years. The dorsum of the right foot is now slightly hyperesthetic. The bulbocavernosus reflex is absent. Lasegue's sign is positive on both sides, but more on the right.

Medicinal Treatment.—Since the operation, hexamethylenamin and potassium iodid were given on alternate days for the first seven weeks, after which the potassium iodid was alternated with an iron, arsenic and strychnin mixture.

Securing a Workable Amount of Function in a Disabled Limb.—It is easy to overlook the importance of training a limb to perform its function more or less regardless of anatomic perfection. It is easy to overlook the fact that, if one joint is defective, other associated joints will make good the deficiency. An illustration of an actual case may be of service. A man with both forearm bones broken has cross-union interfering with pronation and supination. Now the greatest and most powerful movements of pronation and supination take place by means of internal and external rotation of the shoulder joint; therefore, proceed to cultivate that substitute.—Col. H. E. Deane, Gymnastic Treatment for Joint and Muscle Disabilities.

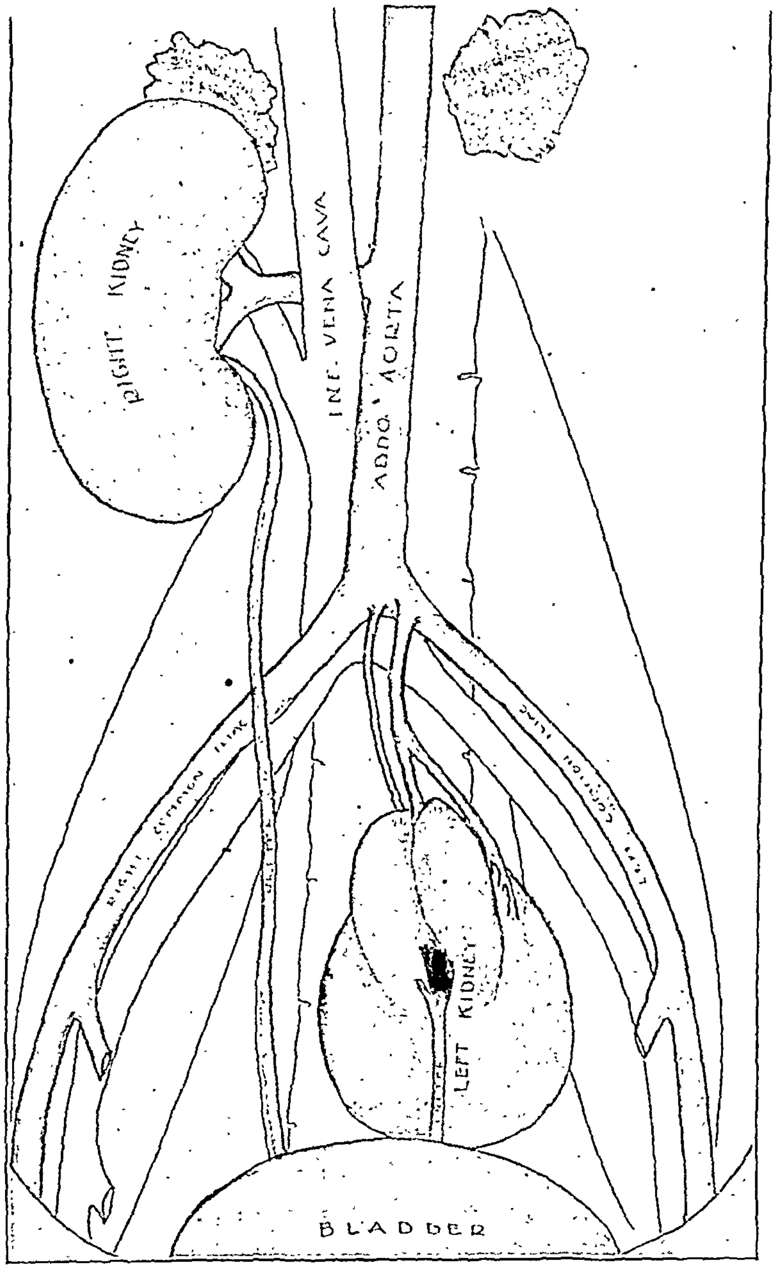
MISPLACED KIDNEY: REPORT OF A CASE

Allen H. Bunce, M.D., Base Hospital No. 43
Captain, M. C., U. S. Army, A. E. F., France

In a necropsy on the body of G. W., a well developed adult male negro, height 5 feet, 11 inches, weight, 170 pounds, who had died of lobar pneumonia, an anomaly in the location, shape and blood supply of the left kidney was observed. The kidney could not be found by feeling in the left renal fossa. After careful dissection the left suprarenal gland, somewhat larger than normal, was located in the usual position. The right kidney and suprarenal gland were in the normal position and had a normal blood supply. The gastro-intestinal tract was removed and the left kidney found inside the bony pelvis slightly to the left side. It was retroperitoneal, as would be expected. The kidney was somewhat pear-shaped, with the small end pointing upward. Its blood supply consisted of a main artery branching from the left common iliac and a smaller branch from the bifurcation of the abdominal aorta. Both arteries entered the anterior surface near the upper end. The veins, two in number, left the kidney on the posterior surface at the upper and lower ends, respectively, and emptied into the left iliac vein. The ureter, which was 9 cm. in length, left the anterior surface of the kidney and passed behind the peritoneum into the bladder in the usual location. The bladder, when distended, partially covered the kidney. The two kidneys, the ureters, the aorta and the bladder were dissected out and removed together. The diagrammatic drawing illustrates the condition clearly.



Location, shape and blood supply (diagrammatic) of misplaced kidney.

INFLUENZA AS SEEN AT THE PUGET SOUND NAVY YARD

C. F. ELY, M.D.
Commander, M. C., U. S. N.

B. J. LLOYD, M.D. (Seattle)
Surgeon, U. S. Public Health Service

C. D. HITCHCOCK, M.D.
Lieutenant, M. C., U. S. N. R. F.

AND

D. H. NICKSON, M.D. (Seattle)
Lieutenant, Junior Grade, M. C., U. S. N. R. F.

NAVY YARD, PUGET SOUND, WASH.

In the present state of our knowledge of this disease, one is tempted to ask, "When is influenza not influenza, and why?" Are we dealing with a definite disease caused by a specific micro-organism? If so, is that organism the influenza bacillus? Is it a hemolytic streptococcus? Is it an aberrant form of the pneumococcus (streptopneumococcus)? Is it a combination of two or more of these, and if so, is infection with the different organisms simultaneous or does the streptococcus follow the influenza bacillus as a secondary invader? May still other organisms than these cause the disease? Are there two or more separate diseases that are being confused both clinically and bacteriologically, and may they coexist in the same patient? May a group of human beings (camp, city or community) be attacked by this epidemic disease and some of them suffer from one infecting organism and some from another and still others from combinations? Are the pathogenic streptococci really a large family that can change form and affinity (for human tissues) and run up and down the scale of virulence ad lib.?

One of us (Lloyd) observed in 1915, 1916 and 1917 that hemolytic streptococci, fatal to rabbits in pure culture (intravenously), could usually be found in certain types of influenza. In one instance he obtained such an organism from the blood (before death) of a patient who had severe cholecystitis, for which operation was performed. The patient recovered, returned home, and became suddenly ill with fever, collapse, signs of pulmonary edema, and intense jaundice. The patient died twenty-one days after operation, and forty-eight hours after the last illness began. It is interesting to note in this connection that in some of the fatal cases of influenza at this station there was marked jaundice.

Nickson also found hemolytic streptococci in the blood of two persons suffering from influenza (bronchopneumonia) previous to his assignment to this station.

Based on previous observations, Lloyd suggested that we would probably find a hemolytic streptococcus the cause of this disease should influenza present itself among our personnel in epidemic form, and also expressed the opinion that a vaccine made from such an organism might be useful as a prophylactic. All of us felt that the influenza bacillus should be added if found. To Drs. Hitchcock and Nickson were assigned the tasks of making the pathologic and bacteriologic studies, following out a more or less definite plan on which all were agreed.

In boldly announcing the fact that this work was undertaken with what might be termed "preconceived ideas" on the part of at least two of us, it might be argued that we were looking for a streptococcus infection. We were; but we were also looking for anything else we could find. Nothing else was found in the blood, nor did we find anything else in the tissues at the necropsies; and a reasonable, though not a persistent, effort was made to obtain the influenza bacillus from the sputum without success. Never did blood cultures show anything but diplococcal or streptococcal forms; only once did tissue cultures show anything else, and that was when they were contaminated by the colon bacillus. Lieutenant Henry reports that in a few cases studied by him at the Seattle training camp he obtained only diplococcal forms, which he regards as pneumococci.

CLINICAL DATA

The onset is sudden. The patient usually has a chill or chilly sensations. There may be headache, and pain in the back; and there is a tendency for the knees to give way. There may be nosebleed. The temperature rises rapidly and may reach 104 or 105. In two fatal cases a temperature of 108 was recorded. The pulse is from 100 to 120, and higher in severe cases. Lung symptoms soon make their appearance with pain over the lungs, usually the lower border. Constipation is the rule, and the patient frequently complains of pain over the upper abdomen.

Examination of the lungs in moderately severe cases shows fine and coarse râles and areas of dulness. The liver and spleen are enlarged and tender. The respiratory rate averages from 28 to 30 and, though higher in very severe cases, there is not the rapid rate seen in ordinary lobar pneumonia. The cough is usually loose, and an abundant frothy, greenish fluid, pink with blood, is brought up. The contrast between this material and that usually seen in lobar pneumonia is quite marked. In severe and fatal cases delirium is present, the facial expression is anxious, and there is often marked cyanosis. In many fatal cases the respiration continued for some time after the heart had stopped.

CLINICAL PATHOLOGY AND PATHOLOGIC ANATOMY

Of sixty-two urinary examinations made fairly early, twenty-six showed albumin and hyaline and granular casts; seven showed albumin only, and twenty-nine were normal.

Of seventy-five blood examinations, twenty-five gave a leukocyte count of 5,000 or less, thirty-four gave a count of between 5,000 and 10,000 and sixteen a count of more than 10,000. Several cases gave a count of from 30,000 to 56,000; but in these cases there was some complication, usually cerebrospinal. In convalescent cases the leukocyte count tends to rise.

Necropsies were performed in thirty-nine cases, only six of which showed varying degrees of consolidation, sometimes complete for some portion of the lung. There was marked engorgement of the lung tissue with a large amount of bloody fluid exuding from the cut surface; not infrequently the cut surface of certain areas showed small amounts of pus in the smaller bronchi. Pleural effusions, varying in amount, usually right sided, serofibrinous, and occasionally purulent, were fairly constant. The heart was slightly enlarged and the right auricle dilated. The kidneys were enlarged and congested, an edematous condition frequently being found about the suprarenals. The spleen was large and soft, the cut surface exuding bloody fluid.

BACTERIOLOGIC FINDINGS

Sputum examinations were made in forty-nine early cases and twenty-five late cases with these results: Smears were made from selected portions. Gram positive cocci were found in pairs and chains, streptococci predominating throughout all examinations. Portions of sputum washed, plated on blood agar and incubated for twenty-four hours showed large numbers of hemolyzing colonies composed (microscopically) of chain-forming cocci (sometimes paired). Subcultures of these in bouillon, with one exception, showed chain formations. Two rabbits were injected intravenously with small amounts of washed sputum, suspended in broth. These animals died after thirty-six and seventy-two hours. Pure cultures of hemolytic chain-forming cocci were obtained from the heart's blood and from the pus from the joints, in both animals.[1]

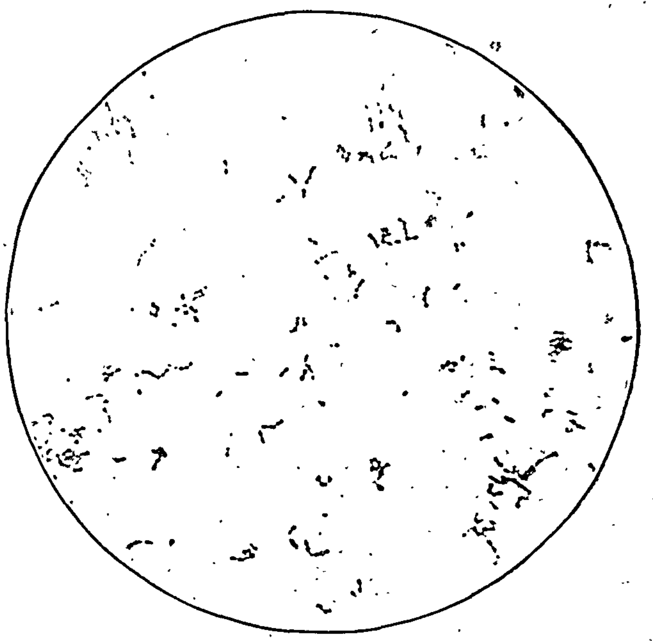

Fig. 1.—Smear direct from pus from joint of rabbit inoculated from washed sputum, × 1,000, showing streptococci.

Cultures made postmortem in twenty cases gave hemolytic streptococci from the heart's blood 17 times; from the pericardium, 12 times; from the liver, 13 times; lung, 14 times; spleen, 5 times; kidney, 17 times; bile, twice. In only one case the cultures were entirely negative. It is believed that this was due to an error in technic. In one case, cultures were contaminated with the colon bacillus.

A total of fifty-two attempts at blood culture on living patients gave twenty-four positive results, all streptococci except one, which gave only a diplococcus, which would not chain. This patient had the physical signs of lobar pneumonia and was clinically fairly typical of that disease; but five members of his family had "influenza" at the same time that he had "pneumonia," all being in the emergency hospital together (civilians). Two patients yielded blood cultures eighteen hours after onset, eight within three days and one after three weeks' illness.

---

[1] Since this was written, one rabbit was killed three weeks after inoculation. It was greatly emaciated; pus from joints was somewhat caseated but showed streptococci.

The technic of blood cultures was as follows: Three c.c. of blood were drawn under aseptic precautions and placed in an Erlenmeyer flask containing 30 c.c. of 1 per cent. glucose broth plus 1 per cent. of sheep serum. After incubating for twenty-four hours there was usually an abundant growth.

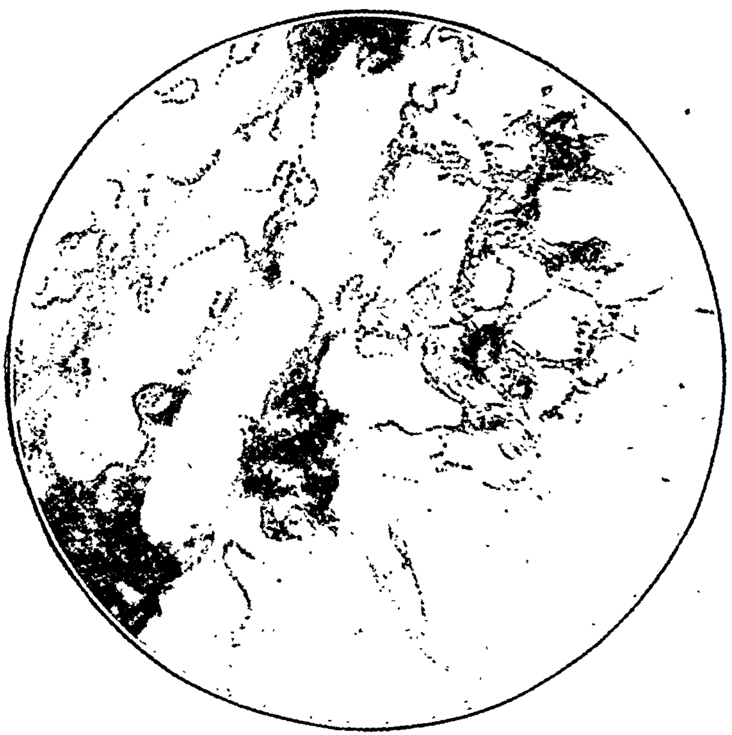

Fig. 2.—Marked chain formation in bouillon culture (twenty-four hours) made direct from human blood from patient who recovered; × 1,000.

CULTURAL AND STAINING CHARACTERISTICS, AND REACTIONS

On tubed solid mediums the organism we are describing grows in small, discrete colonies. On blood agar plates the colonies are usually larger, and when recently from the human body are surrounded by a well marked hemolytic zone. Hemolytic properties are quickly lost in subcultures, but may be restored by passage through rabbits or white mice. The microscopic appearance in smears from human and animal tissues is that of a coccus, occurring in short or long chains; once a diplococcus only was obtained from a blood culture. In the mouse the organism may show as mixed diplococci and streptococci. On agar the growth may also show mixed diplococci and streptococci, or there may be chains of diplococci, and after a few generations bouillon cultures may show diplococci predominating and even groups suggesting staphylococci, though when grown in bouillon direct from human and animal tissues, chain formation is the rule, the units in the chains varying in number from four to twenty. Some strains retained their chain-forming properties much more persistently than others. The size of the organisms varied from 0.3 to 1 micron; they were usually true spheres, but occasionally were somewhat elongated. The development of the organism in broth produces diffuse cloudiness accompanied by varying amounts of sediment. Acid was produced in glucose and lactose 4.6 and 2.1 degrees respectively (phenolphthalein). No gas was produced. The organism is gram-positive and stains readily with the ordinary anilin dyes. A capsule was demonstrated in only one strain from the peritoneal cavity of a mouse. In addition to the hemolytic property noted on blood agar plates, it was found that when 0.5 c.c. of a twenty-four-hour broth culture was mixed with the same amount of a 5 per cent. suspension of red blood cells (rabbit) in physiologic sodium chlorid solution and incubated at 37 C. for one hour, the cells were completely hemolyzed. This was also true of a strain that grew as a diplococcus.

BILE SOLUBILITY

A twenty-four-hour broth culture was filtered through gauze and cotton to remove sediment and large clumps. The filtrate was then centrifuged in Hopkins tubes, the liquid pipetted off and just enough salt solution added to the precipitated organisms to make a distinctly cloudy suspension. Two-tenths c.c. of fresh sterile ox bile was added to 1 c.c. of this suspension and incubated at 37 C. for one hour. Solution of the organisms did not occur. It will be recalled that the organism was obtained direct from the bile at two necropsies.

AGGLUTINATION AND PRECIPITIN REACTIONS

The organism did not agglutinate in Types I, II and III antipneumococcic serum nor in serum from convalescent patients.

A precipitin reaction was obtained in a 1:25 dilution in Type I serum and in a 1:50 dilution in Type III serum. Similar reactions were thus obtained in serums of persons ill of the disease: 1:25, one; 1:50, two; 1:800, one. No others were tried.

PATHOGENICITY FOR MICE AND RABBITS

Injections of 1 c.c. of a twenty-four-hour broth culture into the ear veins of rabbits invariably killed the animals in from eighteen to seventy-two hours. A marked and constant lesion in these animals was a purulent arthritis affecting the larger joints particularly the midjoints of the limbs (corresponding to the elbows and knees). The organism could be demonstrated in great numbers in the tissues and particularly in the pus from the joints, always in chains. Five-tenths c.c. of a twenty-four-hour broth culture invaria-

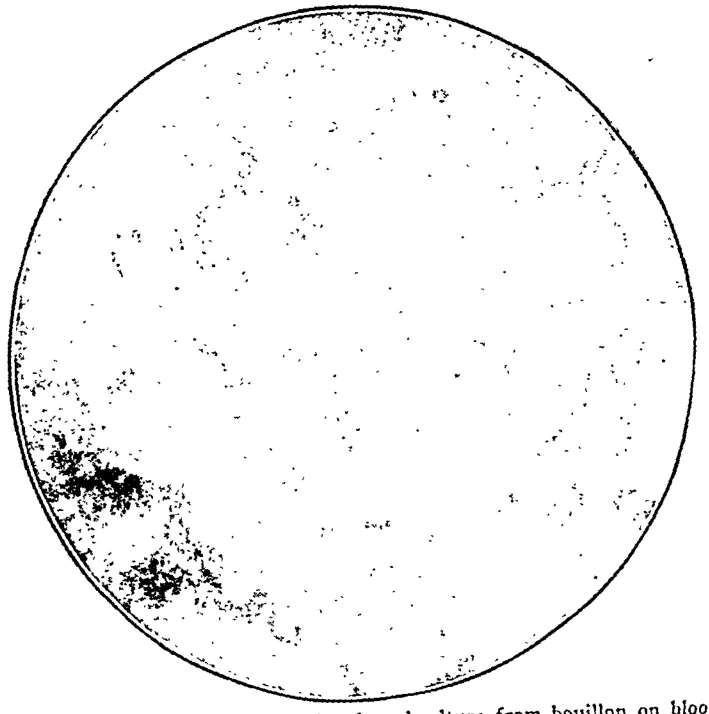

Fig. 3.—Marked chain formation in subculture from bouillon on blood agar plate; × 1,200.

bly proved fatal when injected intraperitoneally into white mice, death occurring in from twelve to twenty-four hours. Smears from the peritoneal fluid showed usually chains, occasionally pairs only, and sometimes both. Cultures made from this fluid, in bouillon, rarely failed to show marked chain formation, even though smears from the fluid showed only diplococci.

TECHNIC OF PREPARATION OF VACCINE

(*a*) Mixed virulent strains of hemolytic streptococci obtained as related are grown for twenty-four hours in 1 per cent. glucose broth plus 1 per cent. sheep serum.

(*b*) At the end of twenty-four hours the supernatant liquid is poured off from the sediment.

(*c*) The organisms from the supernatant fluid are thrown down in a centrifuge.

(*d*) The sediment left in the culture flasks is filtered through gauze and cotton and centrifuged.

(*e*) The two portions of solid micro-organisms are mixed, enough 0.8 per cent. salt solution plus 0.25 per cent. phenol being added to make a heavy suspension. Care should be taken not to add too much salt solution at this stage.

(*f*) The suspension is placed in a sterile bottle with beads and it is shaken to break the clumps.

(*g*) It is filtered again through gauze and cotton.

(*h*) It is filtered again through an alendem filter crucible at 15 pounds pressure; this does not remove the organisms.

(*i*) A small quantity of the filtrate is taken as it comes from the alendem crucible, and by means of a Hopkins tube the number of organisms per cubic centimeter is estimated.

(*j*) Salt solution (plus phenol) is added to make a dilution of 250 million organisms per cubic centimeter.

(*k*) This is tubed, capped and immersed in a water bath for one hour at 56 C.

(*l*) Each tube is tested by planting 3 or 4 drops on blood agar and incubating for twenty-four hours.

The dose used here is 0.25, 0.5 and 1 c.c., given at forty-eight-hour intervals.

INCIDENCE IN VACCINATED AND UNVACCINATED PERSONNEL

Influenza was introduced at the Puget Sound Navy Yard by a draft of men (987 in number) from Philadelphia, many of whom arrived ill or came down within a few hours after reaching this station. A tabulated statement of cases and deaths in the different units is given herewith.

It is fair to say that no unit was divided into two parts for the purpose of running experimental subjects and controls side by side. Circumstances were such that this could not well be done. It is also fair to say that in our largest unit (seamen's barracks) many cases had already occurred before vaccination could be done; we do not know how many. This is also true of the Philadelphia unit. It is not true of the rest of the command.

Conditions of exposure were not materially different in the different units. Conditions of housing differed in that some men were in barracks and some in tents; but this seemed to make no difference with regard to incidence. All of the marines were in barracks, rather closely quartered. All of the Seattle training camp men were in tents, two men to a tent (8 by 10).

The following facts stand out prominently:

Of 4,212 men who were vaccinated, not one man died. Among 111 Filipinos isolated and vaccinated early and later exposed, there occurred only two cases, both the patients recovered. Among 361 marines vaccinated early with no attempt to control exposure, there occurred two cases, both patients coming down after the first injection; both recovered. Among sixty-two marines at the ammunition depot who were vaccinated early, there occurred three cases; two after the first injection and one after the third; there were no deaths. Among 662 bluejackets at the Seattle training camp, three men developed the disease after the first injection, one after the second injection and seven after the third; there were no deaths. Among eighty-three of the Aviation Corps there occurred thirty-two cases, thirty-one of the patients coming down within a few hours after the first injection and

Fig. 4.—Drawing from blood agar plate to show hemolysis (not a very satisfactory picture of the plate).

‡ Thirty-one of the thirty-two came down after the first injection.

eighteen hours after onset, eight within three days and one after three weeks' illness.

The technic of blood cultures was as follows: Three c.c. of blood were drawn under aseptic precautions and placed in an Erlenmeyer flask containing 30 c.c. of 1 per cent. glucose broth plus 1 per cent. of sheep serum. After incubating for twenty-four hours there was usually an abundant growth.

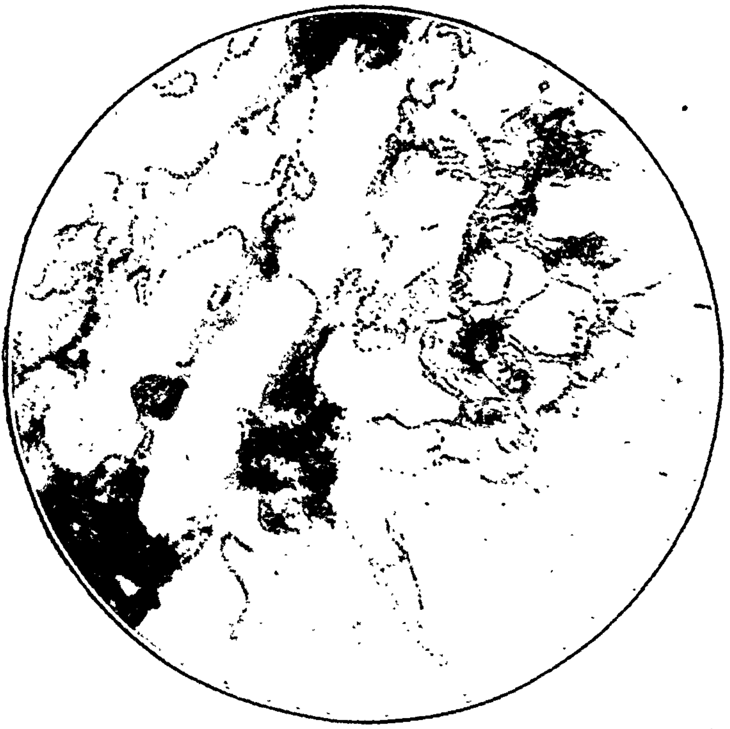

Fig. 2.—Marked chain formation in bouillon culture (twenty-four hours) made direct from human blood from patient who recovered; × 1,000.

CULTURAL AND STAINING CHARACTERISTICS, AND REACTIONS

On tubed solid mediums the organism we are describing grows in small, discrete colonies. On blood agar plates the colonies are usually larger, and when recently from the human body are surrounded by a well marked hemolytic zone. Hemolytic properties are quickly lost in subcultures, but may be restored by passage through rabbits or white mice. The microscopic appearance in smears from human and animal tissues is that of a coccus, occurring in short or long chains; once a diplococcus only was obtained from a blood culture. In the mouse the organism may show as mixed diplococci and streptococci. On agar the growth may also show mixed diplococci and streptococci, or there may be chains of diplococci, and after a few generations bouillon cultures may show diplococci predominating and even groups suggesting staphylococci, though when grown in bouillon direct from human and animal tissues, chain formation is the rule, the units in the chains varying in number from four to twenty. Some strains retained their chain-forming properties much more persistently than others. The size of the organisms varied from 0.3 to 1 micron; they were usually true spheres, but occasionally were somewhat elongated. The development of the organism in broth produces diffuse cloudiness accompanied by varying amounts of sediment. Acid was produced in glucose and lactose 4.6 and 2.1 degrees respectively (phenolphthalein). No gas was produced. The organism is gram-positive and stains readily with the ordinary anilin dyes. A capsule was demonstrated in only one strain from the peritoneal cavity of a mouse. In addition to the hemolytic property noted on blood agar plates, it was found that when 0.5 c.c. of a twenty-four-hour broth culture was mixed with the same amount of a 5 per cent. suspension of red blood cells (rabbit) in physiologic sodium chlorid solution and incubated at 37 C. for one hour, the cells were completely hemolyzed. This was also true of a strain that grew as a diplococcus.

BILE SOLUBILITY

A twenty-four-hour broth culture was filtered through gauze and cotton to remove sediment and large clumps. The filtrate was then centrifuged in Hopkins tubes, the liquid pipetted off and just enough salt solution added to the precipitated organisms to make a distinctly cloudy suspension. Two-tenths c.c. of fresh sterile ox bile was added to 1 c.c. of this suspension and incubated at 37 C. for one hour. Solution of the organisms did not occur. It will be recalled that the organism was obtained direct from the bile at two necropsies.

AGGLUTINATION AND PRECIPITIN REACTIONS

The organism did not agglutinate in Types I, II and III antipneumococcic serum nor in serum from convalescent patients.

A precipitin reaction was obtained in a 1:25 dilution in Type I serum and in a 1:50 dilution in Type III serum. Similar reactions were thus obtained in serums of persons ill of the disease: 1:25, one; 1:50, two; 1:800, one. No others were tried.

PATHOGENICITY FOR MICE AND RABBITS

Injections of 1 c.c. of a twenty-four-hour broth culture into the ear veins of rabbits invariably killed the animals in from eighteen to seventy-two hours. A marked and constant lesion in these animals was a purulent arthritis affecting the larger joints particularly the midjoints of the limbs (corresponding to the elbows and knees). The organism could be demonstrated in great numbers in the tissues and particularly in the pus from the joints, always in chains. Five-tenths c.c. of a twenty-four-hour broth culture invaria-

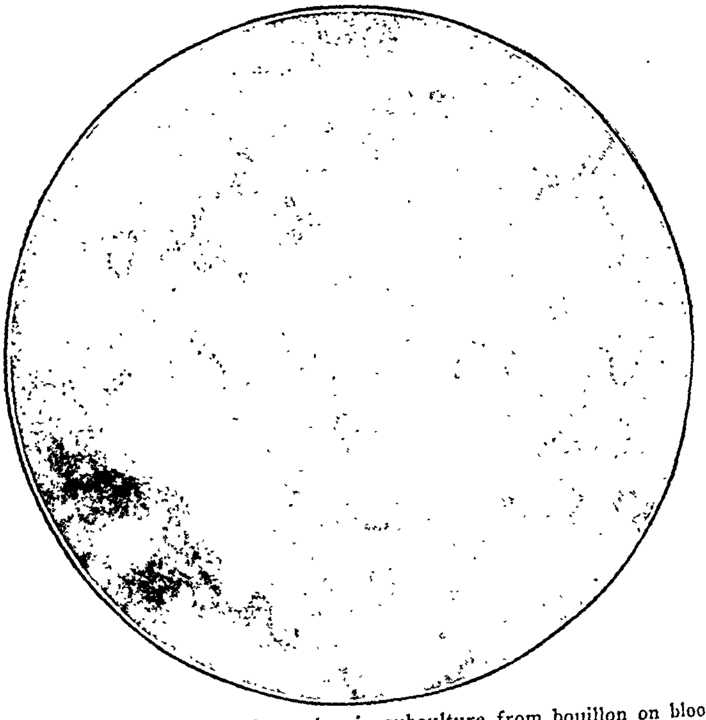

Fig. 3.—Marked chain formation in subculture from bouillon on blood agar plate; × 1,200.

bly proved fatal when injected intraperitoneally into white mice, death occurring in from twelve to twenty-four hours. Smears from the peritoneal fluid showed usually chains, occasionally pairs only, and sometimes both. Cultures made from this fluid, in bouillon, rarely failed to show marked chain formation, even though smears from the fluid showed only diplococci.

TECHNIC OF PREPARATION OF VACCINE

(*a*) Mixed virulent strains of hemolytic streptococci obtained as related are grown for twenty-four hours in 1 per cent. glucose broth plus 1 per cent. sheep serum.

(*b*) At the end of twenty-four hours the supernatant liquid is poured off from the sediment.

(*c*) The organisms from the supernatant fluid are thrown down in a centrifuge.

(*d*) The sediment left in the culture flasks is filtered through gauze and cotton and centrifuged.

(*e*) The two portions of solid micro-organisms are mixed, enough 0.8 per cent. salt solution plus 0.25 per cent. phenol being added to make a heavy suspension. Care should be taken not to add too much salt solution at this stage.

(*f*) The suspension is placed in a sterile bottle with beads and it is shaken to break the clumps.

(*g*) It is filtered again through gauze and cotton.

(*h*) It is filtered again through an alendem filter crucible at 15 pounds pressure; this does not remove the organisms.

(*i*) A small quantity of the filtrate is taken as it comes from the alendem crucible, and by means of a Hopkins tube the number of organisms per cubic centimeter is estimated.

(*j*) Salt solution (plus phenol) is added to make a dilution of 250 million organisms per cubic centimeter.

(*k*) This is tubed, capped and immersed in a water bath for one hour at 56 C.

(*l*) Each tube is tested by planting 3 or 4 drops on blood agar and incubating for twenty-four hours.

The dose used here is 0.25, 0.5 and 1 c.c., given at forty-eight-hour intervals.

INCIDENCE IN VACCINATED AND UNVACCINATED PERSONNEL

Influenza was introduced at the Puget Sound Navy Yard by a draft of men (987 in number) from Philadelphia, many of whom arrived ill or came down within a few hours after reaching this station. A tabulated statement of cases and deaths in the different units is given herewith.

It is fair to say that no unit was divided into two parts for the purpose of running experimental subjects and controls side by side. Circumstances were such that this could not well be done. It is also fair to say that in our largest unit (seamen's barracks) many cases had already occurred before vaccination could be done; we do not know how many. This is also true of the Philadelphia unit. It is not true of the rest of the command.

Conditions of exposure were not materially different in the different units. Conditions of housing differed in that some men were in barracks and some in tents; but this seemed to make no difference with regard to incidence. All of the marines were in barracks, rather closely quartered. All of the Seattle training camp men were in tents, two men to a tent (8 by 10).

The following facts stand out prominently:

Of 4,212 men who were vaccinated, not one man died. Among 111 Filipinos isolated and vaccinated early and later exposed, there occurred only two cases, both the patients recovered. Among 361 marines vaccinated early with no attempt to control exposure, there occurred two cases, both patients coming down after the first injection; both recovered. Among sixty-two marines at the ammunition depot who were vaccinated early, there occurred three cases; two after the first injection and one after the third; there were no deaths. Among 662 bluejackets at the Seattle training camp, three men developed the disease after the first injection, one after the second injection and seven after the third; there were no deaths. Among eighty-three of the Aviation Corps there occurred thirty-two cases, thirty-one of the patients coming down within a few hours after the first injection and

† Fifty-five of the fifty-seven came down after one injection and did not complete the process.

‡ Thirty-one of the thirty-two came down after the first injection.

one after the third injection; there were no deaths. Altogether there were 1,279 men who were vaccinated either before exposure or about the time they were exposed, and of these ninety-four developed the disease before vaccination was completed and eleven afterward. All recovered. Some of the cases in the vaccinated were fairly severe and from the blood of one of these patients a streptococcus was recovered.

The period of observation was from September 17 to Oct. 21, 1918. Up to November 3 there had occurred but forty additional cases at the Seattle training camp and sixteen at the Puget Sound Navy Yard, facts which seem to indicate that the epidemic was practically over at the time these data were obtained. There have been several deaths since October 21, but so far none among those who were vaccinated (November 9).

CONCLUSIONS

We believe that the disease called influenza at the Puget Sound Navy Yard was due to the organism described above, and that despite variations it should be classed as a hemolytic streptococcus, at least until such time as the relationship between diplococci and streptococci is more accurately established. Our findings failed to show that the influenza bacillus was in any way connected with the production of the disease at the Puget Sound Navy Yard.

We believe that the use of killed cultures as described prevented the development of the disease in many of our personnel and modified its course favorably in others. We at first used a single strain, but later mixed two or more strains. We do not know that the latter is advantageous.

Attention is invited to the fact that a vaccine made from streptococci apparently protected 662 blue jackets in a camp where Henry found what he considered pneumococci only.

We suspect that there may be different strains of the organism causing influenza (call it what you please), and recommend for vaccines cultures recently from human tissues, preferably from cases in the same community where the disease is prevalent; such cultures must kill rabbits promptly when given intravenously. One should not forget to add a little serum to the culture medium.

We offer no suggestion with regard to the duration of the immunity produced, and in our experience vaccination may be repeated without inconvenience.

We further suggest that the vaccine be tried out in smaller doses as a therapeutic agent in cases in which there is delayed convalescence, unless there is empyema or other evidence of localized suppuration.

Flatulence and Sleep.—Take the earliest example—the *infant* "muling and puking in its nurse's arms"—keeping its careworn parents awake half the night. Why does the rocking the cradle or "dandling" in the arms so often soothe and produce sleep? Because, owing to the constantly changing axes of the loops of intestines, the bubbles of wind are enabled to pass on. "The hand that rocks the cradle moves the wind." Far better than "ruling the world"! For just the same reason the sleepless adult tosses on his bed from side to side. By doing so he involuntarily coaxes the flatulence to move on from the loops of intestine where it has been accumulating and sending those disturbing messages to the higher centers. And hence many a patient will sleep better after a dose of calomel or blue pill than after one of the recognized hypnotics.—G. King Martyn, M.D., *Medical Press and Circular.*

DEPRESSED FRACTURE OF THE MALAR BONE

A. E. ROCKEY, M.D. (Portland, Ore.)
Major, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

Preparation for the activities of war has made this lesion more frequent than was usual in civil life. It is caused by direct violence of a fall or blow. Automobile or motorcycle mishaps, bayonet and trench drill, mule kicks, and blows in boxing and baseball have been factors in cases brought to our hospital. The extent of the depression, the location of the fracture line, and complicating fractures of other bones differ with the force and direction of the trauma.

In construction, the malar bone itself is more rugged than the maxilla in the immediate vicinity of its articulations. The occasional occurrence of complete or partial anesthesia of the area of distribution of the infra-orbital nerve demonstrates definitely that the fracture line runs through its foramen of exit. The orbital plate is also involved. The temporal process may or may not be broken. Emphysema was present in one case. When depression is slight, the external aspect may be speedily covered by the resulting swelling. It is consequently not discovered until the swelling subsides and the deformity becomes manifest.

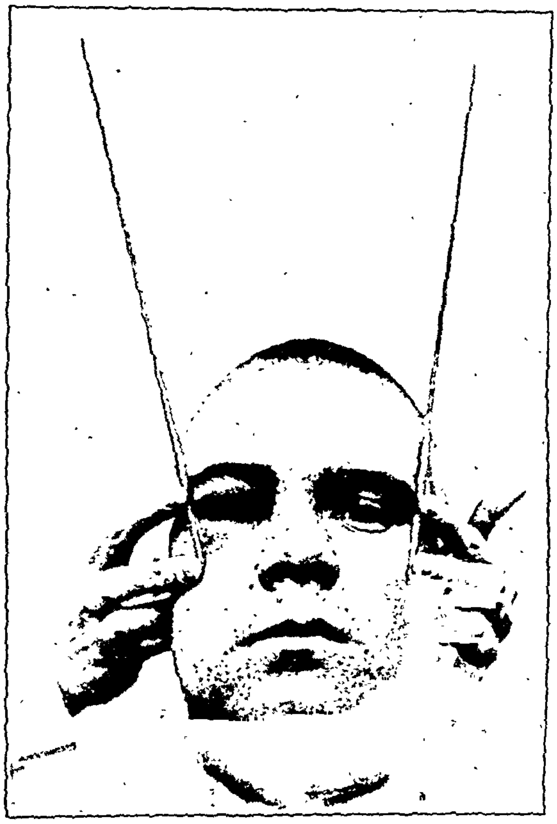

Fig. 1.—Method of diagnosis in depressed fracture of the malar bone.

We have devised a method of diagnosis, illustrated in Figure 1, which definitely determines even a slight depression. Two straight wooden applicators are placed, vertically at the outer edge of the orbit from the prominence of the cheek bone upward, as shown. If depression exists, the difference in angle is obvious. The swelling may be pushed out with the finger tip and the end of the applicator given firm rest on the bone.

The bone may usually be easily raised into position by grasping it through the skin with heavy tenaculum forceps. The ordinary towel clips at hand in every surgery answer the purpose admirably. A general anesthetic must be given. Gas does well, as the operation is short.

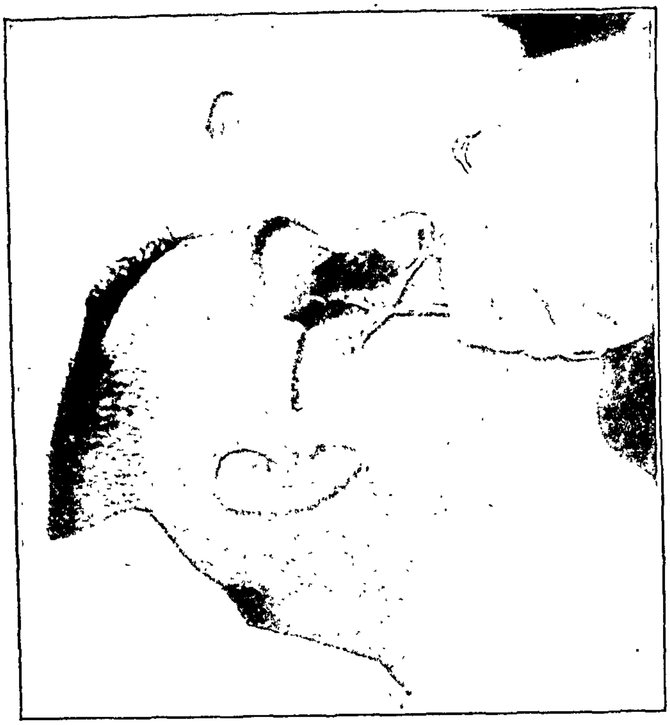

Fig. 2.—Raising of bone by heavy tenaculum forceps.

Figure 2 illustrates the operation. The photograph was taken just as the bone had been raised into place. Figure 3 shows the position of the grasp.

The operator must satisfy himself, both by palpation and by reapplication of the test, that the normal position has been attained. As a rule, when raised, the bone sticks well in place. In one case, during the palpation to determine its position, it slipped down and had to be raised a second time. Caution should be observed to protect the cheek from external pressure until it is well fixed by healing.

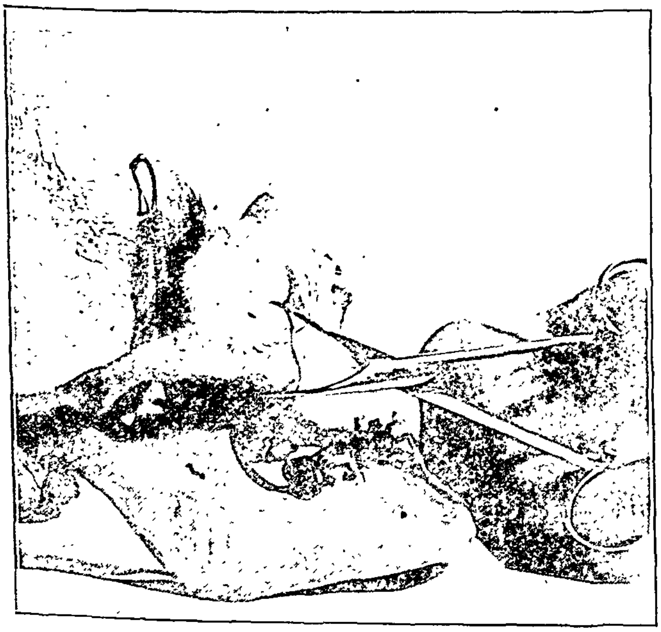

Fig. 3.—Position of grasp.

The facility and accuracy of this method may obviate the flat cheeks that are permanent deformities unless timely correction is made.

RUPTURE OF ENCAPSULATED EMPYEMA INTO THE PLEURAL CAVITY

REPORT OF TWO CASES

HENRY M. THOMAS, JR., M.D., (BALTIMORE)
First Lieutenant, M. C., U. S. Army
CAMP MEADE, ADMIRAL, MD.

Following the recent epidemic of influenza at the base hospital, Camp Meade, Md., there were observed two cases that presented a syndrome altogether new to those of us who saw them. We are familiar with cases of empyema rupturing into a bronchus, and have read of cases rupturing externally, but we have nowhere seen described the striking condition brought about by the rupture of an abscess or encapsulated empyema into the pleural cavity. The serious nature of such an occurrence, as shown by the death of one patient in thirteen hours and the desperate condition of the other when operated on, the probable fatal outcome of all cases undiagnosed, and the possibility of saving the patient's life by a prompt recognition of the condition coupled with surgical interference, makes the report of these two cases desirable. Occurring as a sequel of the influenzal pneumonia that has swept through all the camps, it seems probable that our experience will be duplicated elsewhere.

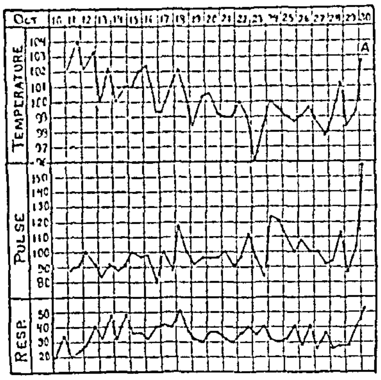

Fig. 1 (Case 1).—Temperature curve, showing patient's improvement until the rupture of the encapsulated empyema. *A*, died, 12:30 p. m.

REPORT OF CASES

CASE 1.—J. E., a private of the supply company, Thirty-Third Field Artillery, was admitted to the base hospital, Oct. 10, 1918, from Evacuation Hospital No. 38, where he had been treated since October 6 for influenza. A diagnosis of bronchopneumonia was made. On admission the physical examination showed both lungs full of moist râles; over both bases behind, the breath sounds were bronchovesicular and the percussion note was impaired. These lung signs remained about the same until October 29, when the right lung was found to be clearing up, but râles were still present throughout the left lung; his temperature had not gone above 100 for a week, and his general condition was much improved.

October 29 at 11 p. m., the patient suddenly complained of a severe pain in the right axilla which was made worse by deep inspiration; a soft pleuritic rub was heard low in the right axilla. One sixth grain of morphin gave no relief, and his condition gradually became worse until 4 a. m., October 30, when the officer of the day was called. He found the patient in an alarming condition; pulse, 160; respiration, 52. He was obviously ill and apprehensive; his dyspnea was extreme, and each shallow breath was evidently attended by much pain. The pain at this time was localized in the right abdomen, which was found to be markedly distended; the abdomen was tender throughout, but more so on the right side; and the liver dulness was obliterated by tympany. His condition was thought to be due to some acute abdominal complication, such as perforation, but the quality of his pulse was so poor that no surgical interference was undertaken. One eighth grain of morphin only slightly ameliorated the symptoms, and a soapsuds enema did not relieve the distention. At 8 a. m. the patient's condition was the same.

At 10:30 a. m., a careful examination of the chest revealed the fronts clear; in back on the right side below the angle of the scapula, the percussion note was flat and the voice and breath sounds had a distant quality. Fluid was suspected in the right chest, but the abdominal symptoms were so prominent and the patient was so completely in a state of shock that its place in the picture seemed unimportant. The white blood count was 71,500; differential count revealed: polymorphonuclears, 95 per cent.; small mononuclears, 4 per cent.; large mononuclears, 1 per cent.

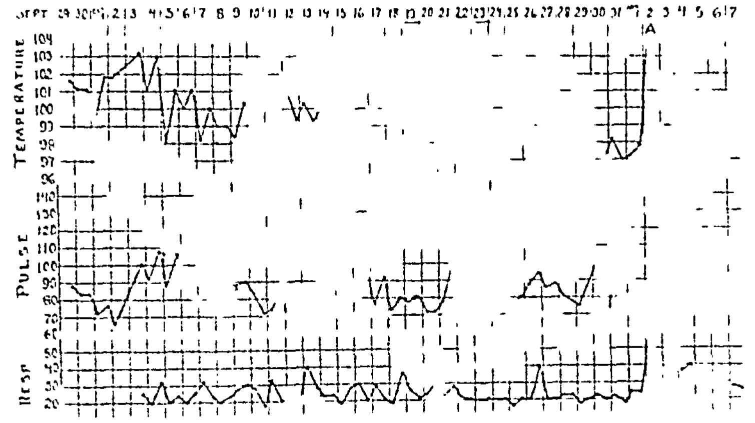

Fig. 2 (Case 2).—Temperature curve, showing patient's improvement until the rupture of the encapsulated empyema, and course following operation. *A*, thoracotomy.

At 12:30 p. m. the patient died.

A postmortem examination revealed the right lung compressed by about a liter of thin, dirty "dish-water" pus from which a hemolytic streptococcus was grown. The lung was tightly tied down to the diaphragm by strong adhesions. In the fissure between the upper and lower lobes, there was an old pocket which might have contained several drams of pus. The compressed right lung showed some areas of pneumonic consolidation. The left lung was essentially normal on gross examination. The intestine was markedly distended; otherwise the abdomen yielded nothing of interest. The cause of death was empyema of the right side complicating bronchopneumonia.

At a loss to explain the sudden change in the condition of the patient and his subsequent early death, we were forced to the conclusion that a rapid absorption of toxins from a large area of serous membrane, associated with a sudden accumulation of fluid, had taken place. The rupture of an encapsulated empyema into the pleural cavity seemed a reasonable assumption as to the cause of the sequence of events, which had simulated quite closely the rupture of an appendical abscess.

Three days later the second example of this syndrome occurred, and the outcome made us feel that our conception of the course of events in the first case had been essentially correct.

Case 2.—C. L., a private of Company K, Seventeenth Infantry, was admitted to the base hospital, Oct. 2, 1918, from Evacuation Hospital No. 38, where he had been ill since September 28 with influenza. A diagnosis of bronchopneumonia was made. The patient improved rapidly and, October 28, was allowed to be up and around the ward, at which time there were noted a few râles over both lungs behind, but no signs of any consolidation or fluid.

November 1, at 7 p. m., while raising himself from lying across a bed, the patient suddenly felt a sharp pain in his left side. Physical examination failed to reveal any abnormal chest findings.

November 2, at 9 a. m., after a sleepless night, his temperature was 104, pulse, 140 and thready, and respiration, 58. From a condition of apparent health the patient had rapidly passed into a critical state in the course of a few hours. His eyes were bright, cheeks flushed, and breathing shallow and very rapid, accompanied by an expiratory grunt. The left lung showed tubular breathing and flat percussion note over base below the angle of the scapula extending to the anterior axillary line; over the right back below the seventh rib, the percussion note was flat and the breath and voice sounds were markedly diminished. The abdominal muscles were rigid, and tympany extended up over the costal margin as high as the sixth rib on the right side. The white blood count was 41,000; polymorphonuclears, 98 per cent.; small mononuclears, 2 per cent.

Thoracentesis in the eighth interspace below the angle of the left scapula yielded 150 c.c. of turbid "dish-water" pus which, when examined, showed many cocci occurring singly and in pairs (on culture, the pneumococcus).

Three thoracenteses on the right side yielded negative results, the signs probably being due to extreme upward displacement of the liver by tympanites in the rigid abdomen. Removal of the fluid seemed to give the patient slight relief, but his condition was critical.

At 3:30 p. m. thoracotomy was done and a large amount of pus was slowly drained from the left chest, following which, his condition improved slightly.

November 3, the patient being definitely better, the Carrel-Dakin treatment was begun. From then on his improvement was satisfactory.

ESSENTIAL FEATURES OF THIS SYNDROME

During a more or less normal convalescence, the patient feels a sudden, sharp pain in some part of the chest, brought on by a slight exertion. In a few hours he becomes critically ill; the temperature rises sharply to from 102 to 104; the pulse is rapid and thready; the respirations are between 50 and 60 a minute, shallow and extremely painful. The eyes are bright, the cheeks flushed, and the expression is anxious. Mentally the patient is alert and fully aware of his critical condition. The pain is localized in the lower part of the chest or entirely in the abdomen.

On examination, the abdomen is found to be greatly distended, marked tympany extending well up over the liver, and the tenderness, which is general, may be more marked on one side than on the other. The chest findings are not striking, but may show evidence of a small amount of fluid at one base. The white blood count reveals an extraordinary polymorphonuclear leukocytosis. The patient's condition becomes progressively worse, with no change in the picture except for increasing prominence of the signs of fluid in the chest.

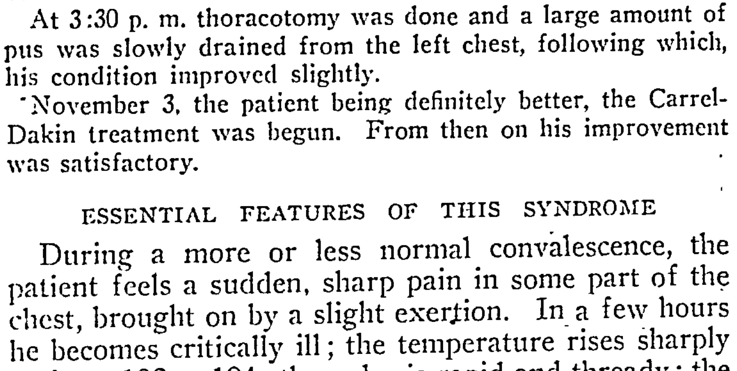

Fig. 3 (Case 3).—Temperature curve, showing course prior and subsequent to operation. *A*, thoracotomy.

COMMENT ON CASES

The prominence of the abdominal symptoms and the extreme prostration of the patient led us in the first case to a faulty diagnosis. In retrospect, however, we were impressed by the absence of vomiting, which would have been expected in a case of general peritonitis.

What occurred, then, was the rupture of a small encapsulated empyema and the quick spread of pus over a large area of the pleural surfaces. As the pleura reacted, a rapid accumulation of fluid took place in the pleural cavity, pushing the lung up and tugging on the adhesions which, in the first case, bound the lung tightly to the diaphragm. The toxemia, owing to the rapid absorption of pus from a serous membrane rich in lymphatics, produced the remarkable reaction that caused sudden collapse. The meteorism and leukocytosis were indexes of the severity of the reaction. The pleuritic pain, coupled with the abdominal distention, explains, though somewhat inadequately, the extraordinary degree of dyspnea. We believe that satisfactory treatment of this condition depends on its early recognition and free drainage of the pleural cavity, thoracotomy being the procedure of choice.

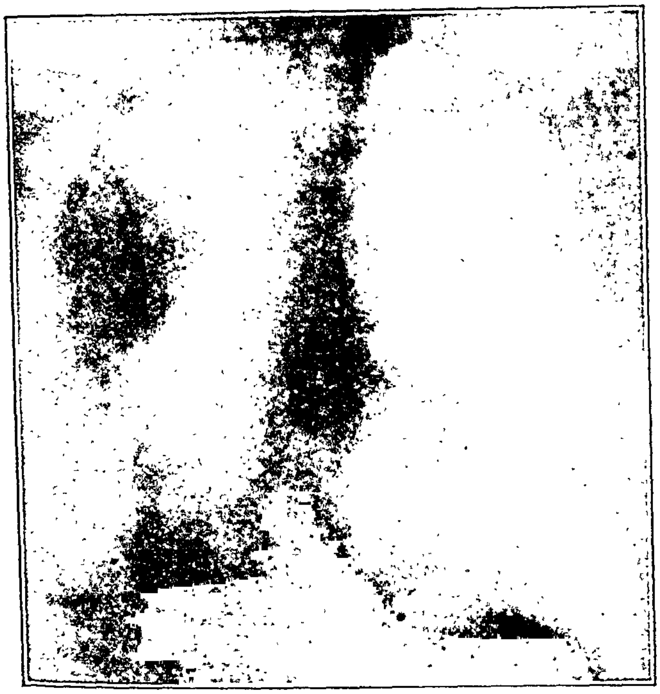

Fig. 4 (Case 3).—Encapsulated empyema which gave no physical signs, being covered completely posteriorly by the scapula and anteriorly and laterally by air-containing lung.

A third case accidentally revealed by the roentgen ray is interesting in connection with the two just discussed:

Case 3.—S. L., a private of Company 6, One Hundred and Fifty-Fourth Depot Brigade, was admitted to the base hospital, Sept. 28, 1918. A diagnosis of influenza was made.

October 2, bronchopneumonia of the right lung was discovered, and three days later the temperature reached normal. During the next three weeks the patient's convalescence was satisfactory, except for an occasional evening rise of temperature to 100 or 101.

October 28, the physical signs at the right apex suggested the possibility of the condition being a flare-up of an old pulmonary tuberculosis, and so a roentgenogram was made (Fig. 4). This plate showed the presence of an encapsulated empyema entirely covered posteriorly by the scapula and anteriorly and laterally by air-containing lung tissues. At operation about 400 c.c. of thick pus (on culture, pneumococcus) was removed.

Without the aid of a roentgen examination and the subsequent surgical treatment, this case might have followed a course similar to that of Cases 1 and 2.

Two other cases very similar to this one have been observed since our attention was directed toward them.

The prevalence of pneumonia at this time, the impossibility of having a roentgenogram made of every patient, and the lack of physical signs or symptoms preceding this condition, make it probable that other such cases will occur in the near future, and we hope that our experience will prove helpful to others.

PROPHYLACTIC INOCULATION AGAINST RESPIRATORY INFECTIONS

DURING THE PRESENT PANDEMIC OF INFLUENZA
PRELIMINARY REPORT *

E. C. ROSENOW, M.D.,
ROCHESTER, MINN.

In attempting to lessen the incidence and to reduce the severity of infections of the respiratory tract by vaccination, it is essential to consider the wide range of bacterial flora, the relative prevalence of each species, as well as the fluctuations in incidence and severity of these infections with changes in season. The well-defined tendency of bacteria of the same species to localize differently in different epidemics indicates peculiar infecting and antigenic powers. The short duration of immunity to infections following attacks adds greatly to the difficulty. However, owing to the high incidence and high mortality rate from infections of the respiratory tract during the present epidemic, a painstaking effort to raise the resistance of individuals by inoculation with appropriate vaccines appeared to be strongly indicated.

In considering prophylactic inoculations in this epidemic of influenza, we put aside the debated question as to the cause of the initial symptoms and considered primarily the possibility of immunizing persons against the bacteria, pneumonia, streptococci, influenza bacillus and staphylococci, which are conceded by all to be the common causes of death in this disease. It was thought that it might be possible to raise to some degree, by artificial means, the immunity of persons to these micro-organisms to which they appear so susceptible, and thus to lower the incidence of the more serious respiratory infections, particularly pneumonia.

The bacteria found as the cause of the complications in this epidemic appear to have exalted and peculiar infecting powers. The mode of death and the findings in the lungs, for example, in the so-called acute bronchopneumonia following influenza, are quite unique and are strikingly similar, irrespective of the species of micro-organism present. Infection of the lung by hemolytic streptococci without empyema and without tonsillitis indicates peculiar localizing power of this micro-organism. The influenza bacillus appears to have acquired peculiar virulence. The frequency of staphylococci in the sputum and lung associated with pneumococci and streptococci far exceeds that which occurs in lobar pneumonia. A study of the various strains isolated has revealed commonly marked variations in cultural and other properties. Owing to

---

* From the Mayo Foundation.

* Read before the American Public Health Association, Chicago, Dec. 10, 1918.

these findings, it was the plan to prepare the vaccine not from saprophytized laboratory strains, as is too often the rule in vaccine therapy, but from strains freshly isolated from the sputum and lungs, and to incorporate the bacteria in the vaccine in about the proportion in which they are found, and before the more or less peculiar properties disappear. A bacteriologic study, made during the progress of the epidemic, showed a decided change in the bacterial flora, and hence new strains were added from time to time in order that the vaccine might represent as nearly as possible the bacterial flora of the disease at various stages of the epidemic.

Heretofore lobar pneumonia has been unusually prevalent for some months following epidemics of influenza. It was felt that this would be particularly apt to be the case following the present epidemic, since it began early in the season. It was decided, therefore, to include a series of the fixed types of pneumococci in the vaccine, although they were infrequently isolated, especially during the early part of the epidemic.

A study of the secretions from the nose and throat, of the sputum and lung exudate, from the very beginning of the epidemic as it occurred in and about Rochester, revealed commonly, among other bacteria, a streptococcus having some distinctive features. Smears from the nose and throat and sputum at the onset of the attack show quite constantly large numbers of this organism in the form of gram-positive lanceolate diplococci occurring singly, but more often in rather long chains. The epithelial cells are frequently found packed with this micro-organism. On artificial cultivation of these exudates it presents morphologic and cultural features both of the pneumococcus and of *Streptococcus viridans.* It produces on isolation a rather moist, spreading, nonadherent, greenish colony on blood agar plates, and a diffuse cloud in glucose broth. On solid mediums it grows as a lanceolate diplococcus of quite uniform size, and usually is surrounded by a distinct capsule. In glucose broth it produces lancet-shaped diplococci in rather long chains. Smears from the older cultures often show extreme variations in size and shape. Injection of sputum into guinea-pigs is usually followed by death from peritonitis, the peritoneal exudate and blood showing this organism in pure or almost pure form. It is more virulent than the green-producing streptococci from the throats of normal persons, but is less virulent than pneumococci from lobar pneumonia. The strains do not usually ferment inulin. It does not autolyze readily and is not soluble in bile. Owing to these findings the vaccine was made to contain a heavy mixture of these strains.

The organism is undoubtedly the one found by the English investigators and designated by them as diplostreptococcus, and the one found by Mathers and for which Tunicliff finds an increased opsonic content in the serum of convalescent patients. Immunologic and other studies to determine further the relations of this organism to influenza are under way and will be reported later.

Hemolytic streptococci were found next most frequently, particularly in fatal cases during the first half of the epidemic. *Staphylococcus aureus* and influenza bacilli appear to play a minor but definite rôle in the production of the complicating pneumonia in some cases. Hence, examples of strains of hemolytic streptococci, staphylococci and influenza bacilli were included in the vaccine.

PREPARATION OF THE VACCINE

The formula of the vaccine used during the earlier part of the epidemic, and exclusively in the cases in this report, is given in Table 1. The bacteria were grown for from eighteen to thirty-six hours at from 33 to 35 C., in 0.2 per cent. glucose broth. The broth was autoclaved at 20 pounds pressure for from one to two hours to insure freedom from living spores. The glucose was added in a sterile manner from a concentrated sterilized solution in water. It was found that the cultures of pneumococci and streptococci yielded approximately 1,000 million bacteria, and *Staphylococcus aureus* 2,000 million bacteria per cubic centimeter. Luxuriant growth (about 1,000 million per cubic centimeter) of the influenza bacillus was obtained by adding approximately 1 c.c. of laked human blood per liter of glucose broth. The strains were grown separately in the flasks. Smears were made before centrifugation of each flask to eliminate possible contaminations. The pneumococci and allied green-producing streptococci, the staphylococci and influenza bacilli were separated from the broth culture by centrifugation,[1] and then suspended in sodium chlorid solution. At first 50 per cent. of the hemolytic streptococci were added in the form of the killed broth culture, and the other 50 per cent. in sodium chlorid solution suspension after centrifugation. But owing to rather severe reactions, only 25 per cent. of the hemolytic streptococci are added in the form of the broth culture. The streptococci in the broth culture are killed by the addition of 0.5 per cent. cresol. The centrifugated bacteria are suspended in sodium chlorid solution so that 1 c.c. represents approximately the growth from 50 c.c. of the broth culture, and are killed by the addition of from 1 to 1.5 per cent. purified cresol. The dense suspensions are diluted with an equal volume of sodium chlorid solution after the cultures, made twenty-four hours after the cresol is added, have remained sterile for forty-eight hours. In some instances the suspensions became slightly contaminated with *Bacillus subtilis,* when heating to 60 C. for one hour was necessary to render them completely sterile. If this was not sufficient, the suspensions were discarded. At first, owing to the urgent demand for the vaccine, the use of extreme heat in the sterilization of the broth, negative aerobic and anaerobic cultures at the end of from forty-eight to seventy-two

Pneumococci Group IV and the allied green-producing diplostreptococci described	30 per cent.
Hemolytic streptococci	20 per cent.
Staphylococcus aureus	10 per cent.
Influenza bacillus	10 per cent.

---

[1] In connection with some work on poliomyelitis in which it became necessary to procure large quantities of the streptococcus, the ordinary large cup centrifuge proved inadequate. A number of centrifugal machines were tested to see if they might not facilitate greatly the clarification of broth in its preparation and to separate efficiently the bacteria from large quantities of liquid cultures. A number were found useful; but owing to the simplicity of construction and the ease with which bacteria may be obtained from the revolving bowl without contamination, the one manufactured by the Sharples Separator Company, West Chester, Pa., was selected and has proved satisfactory for the purpose. By the use of the small laboratory size, it is possible, for example, to separate the bacteria from 50 liters of broth an hour. The revolving bowl and other utensils with which the broth comes in contact are autoclaved. A galvanized iron hood built over the machine makes it possible to sterilize the air in the hood with steam; and by siphoning the broth cultures from the bottles, large quantities of bacteria may be collected without contamination.

hours were considered sufficient as sterility tests. It is now the rule to hold the vaccine until all cultures and animal tests have proved negative for one week. Blood agar and glucose broth and glucose brain broth and litmus milk in tall columns are the mediums used for the sterility tests. The vaccine is finally made up by diluting the dense suspensions in the proper proportions with sodium chlorid solution so that 1 c.c. contains approximately 5 billion bacteria. Purified cresol (0.3 per cent.) is used as a preservative. The initial dose for adults is 0.5 c.c. subcutaneously. This is followed in one week by 1 c.c. The third dose is given fourteen days after the first dose, and consists of 1.5 c.c. The doses in children are 0.1, 0.2 and 0.3 c.c. or more according to age. Owing to the relatively large doses, intervals shorter than one week between injections are considered inadvisable.

RESULTS

In most instances there is a moderate local reaction. Constitutional symptoms are usually mild or absent. Both local and general reactions are decidedly less than those following typhoid vaccines. Exceptionally severe reactions occur showing unusual individual susceptibility. The severer reactions are prone to occur in persons who give a history of recent exposure to the disease, or who already have beginning symptoms of it. In these persons, attacks may appear to be precipitated by the vaccination; but the course is usually short and relatively mild. Persons appear to be more sensitive to the vaccine during the incubation period than before or after the attack is established, or following recovery.

Physicians, nurses and employees of the several hospitals in Rochester were first inoculated. After it was determined that injections of the vaccine were followed by an increase in antibodies in the serum, that the inoculations appeared to be quite harmless, that there was no increased incidence of respiratory infection following the inoculations but an apparent decrease instead, it was decided to study its effects on a larger scale as the epidemic became acute. The vaccine was sent gratis for study by the Mayo Foundation to hospitals and physicians on request, on condition that reports of results be furnished.

TABLE 2.—INCIDENCE OF ILLNESS AND MORTALITY FOR ONE THOUSAND PERSONS

	Inoculated					Uninoculated
	After First Inoculation	After Second Inoculation	Within 7 Days after Third Inoculation	Within 6 Weeks after Third Inoculation	Total	
Influenza	23	10	9	14.6	56.6	229
Pneumonia	1.8	1	1	1.8	5.6	15.7
Meningitis	0	0	0	0	0	0.4
Encephalitis	0.04	0	0.05	0	0.09	0.2
Deaths from influenza, or pneumonia	0.63	0.08	0	0.19	0.9	3.4
Total number of inoculated and uninoculated persons	28,459	26,150	20,792	20,792	....	61,753

The reports included in this paper are from physicians, hospitals and other institutions, chiefly from cities and towns within a radius of 200 miles from Rochester.

In Table 2 is given a summary of the results obtained in a considerable number of inoculated and uninoculated control persons. The reports containing results in the vaccinated after the epidemic was on the decline are not included. The uninoculated represent such persons in institutions, colleges, factories, corporations and communities where the vaccine was used. Only those reports are included that contain accurate data as to the incidence and mortality among the uninoculated. The age in both the inoculated and the uninoculated falls mainly between twenty and forty years. The observations were made from Oct. 15 to Dec. 8, 1918. It will be seen that there was no apparent negative phase following the first inoculation and that there was a progressive diminution of incidence and death from influenza and pneumonia following the successive inoculations. The total incidence of recognizable influenza, pneumonia and encephalitis in the inoculated is approximately one-third as great as in the control uninoculated. The total death rate from influenza or pneumonia is only one-fourth as great in the inoculated as in the uninoculated. No cases of meningitis occurred in the former, whereas in the latter there were 0.4 per thousand. These results were obtained by including all persons who developed influenza or pneumonia and all who died from the day of the first inoculation, and 7,667 persons, or about one fourth of the total number who received only one inoculation.

The total incidence and death rate in the uninoculated controls are well within the average, as they occur during the present epidemic and hence serve as a fair basis for comparison. Experiments in which alternate control persons were inoculated were not done because of difficulty to obtain consent, and because, after all, the results from prophylactic inoculation must be sufficiently favorable to be apparent under the conditions included in this report.

All but two of over seventy physicians who have used the vaccine report that the attacks of influenza, if contracted by the inoculated, are milder and of shorter duration, and that convalescence is more rapid than in the uninoculated. This agrees with our observations, and is in keeping with the lower death rate among the inoculated. This difference has been noted in communities in which the incidence and mortality rate were exceptionally high as well as where they were comparatively low. In view of this observation, granting that the initial symptoms in influenza may be due to an unknown virus, the lowered incidence of influenza among the inoculated may be only apparent. The attacks may have been so mild as to escape detection.

Among the nurses at St. Mary's Hospital, Rochester, where fourteen developed influenza within two days prior to the first inoculation, only one case developed subsequently during a period of six weeks. Similar apparent protection was afforded to the personnel of other hospitals following vaccination. At the State Hospital for the Insane at Rochester, with a total population of about 1,500, where one case of influenza had occurred before the inoculations were given, only three cases occurred following the date of the first inoculation for a period of six weeks. With the occurrence of the second wave of the epidemic, however, there occurred a mild outbreak of the disease. This would indicate that the immunity is of short duration.

Nearly all of the patients with influenza and pneumonia admitted for treatment in the hospitals in Rochester, where approximately one half of the population has been vaccinated, have been from the uninoculated group, excluding those patients who contracted the disease elsewhere.

In one hospital in which the nurses had been inoculated, no cases developed after the inoculations, although the nurses continued to care for patients with influenza. Owing to the scarcity of vaccine, some of the nurses, living under identical conditions, were not inoculated, and a high percentage of these contracted severe attacks.

Numerous instances have been observed in which protection appeared to be afforded to inoculated members of families of which all the uninoculated became ill. Similar results were obtained when conditions among the inoculated and uninoculated were comparable, such as in offices, factories and schools, where nearly all were inoculated, or where only a small percentage were inoculated. Illustrating results are as follows:

Of 1,000 persons employed by one company, 481, about one half, received one inoculation; 224 received two inoculations, and ninety-five received three inoculations. From October 28, the date of the first inoculation, to December 8, 138 cases of influenza occurred, only twenty of which were among persons who had had one or more inoculations. Of these, fourteen had had only one inoculation, and the remaining six had but two inoculations. There were thirteen deaths, only two of which followed influenza among the inoculated, and in these two cases only one inoculation had been given.

The mortality from bronchopneumonia in pregnant women has been especially high during the present epidemic. The vaccinations in a fairly large number of such persons appear to have afforded some protection against this complication. The bacteria included in the vaccine belong to the general group of microorganisms associated commonly with chronic infections, such as arthritis, sinusitis and bronchitis; hence some effect should follow its injection. Striking instances of improvement in these conditions have been noted but whether due to specific or nonspecific effects or whether the vaccine acts as an "exfoliative stimulus" according to Larson, liberating preformed specific antibodies, remains to be determined.

From the results obtained thus far, it appears possible to afford a definite degree of protection by prophylactic inoculation to persons against the more serious respiratory infections during the present epidemic of influenza. The duration of immunity is not known, but indications are that it is relatively short.

The vaccine should contain freshly isolated strains of the more important bacteria in approximately the proportions as found in the sputum and lungs in the disease, and since the relative proportions of the bacteria at hand differ so markedly in widely separated communities, judging by the reports, the formula of the vaccine should be made to conform as nearly as practicable to the respective flora of the disease in the communities in which the vaccine is to be used.

A saline vaccine was used as an emergency measure. Owing to the large number of different bacteria that need to be included and the large doses necessary, a lipovaccine, judging by the recent work of Whitmore, ought to possess definite advantages, since reactions should be less severe, the formation of antibodies more marked, and the resulting immunity more enduring.

I am constantly being asked with regard to the use of the vaccine in treatment. Since the severer complications in influenza, such as pneumonia, do not usually begin until the fourth day or later, the vaccine, if given at the onset of the disease might reasonably be expected to afford some protection. The initial prophylactic dose daily for one, two or three days, provided no unfavorable symptoms occur, is recommended. The results obtained are considered preliminary, and final conclusions cannot be drawn at this time. It is indicated that the vaccine used was at least harmless, that a certain degree of protection was afforded, and that prophylactic inoculation against the respiratory infections, so fatal during this epidemic, be studied on a large scale by many according to the principles herein laid down.

TREATMENT OF INFLUENZAL PNEUMONIA WITH PLASMA OF CONVALESCENT PATIENTS*

JOHN J. O'MALLEY, M.D.
Lieutenant-Commander, M. C., U. S. Navy
AND
FRANK W. HARTMAN, M.D.
Lieutenant, M. C., U. S. Navy
WASHINGTON, D. C.

The addition of 33⅓ per cent. to the normal population of Washington during the past eighteen months has given us a great military camp with barracks-like overcrowding, yet there is nothing comparable to the military supervision of health conditions.

In the present epidemic, the Medical Department of the Navy is treating not only the officers and their families and the enlisted personnel, but also all civilian employees. Up to December 16, 567 cases of influenza and complicating pneumonias were treated at the Naval Hospital. Of these, 157, or 27.8 per cent., either came in with pneumonia or developed it during the residence.

Without going into the clinical picture of the disease, we may say that the outstanding feature is an overwhelming toxemia. Characterized by headache, muscular fatigue and pain, mental dulness, leukopenia and in many cases nausea and vomiting. Nature's forces, thus paralyzed, failed to respond to ordinary therapeutic measures, especially when pneumonia of whatever etiology complicated the disease. Two factors, we believe, aided in keeping our mortality percentage low in the first days of the epidemic, namely, digitalis and venesection. Isotonic glucose and sodium bicarbonate intravenously and massive doses of camphorated oil were each given in a series of cases without beneficial results. In the later stages venesection was most efficacious in combating dilatation of the heart and flooding of the lungs. Time and again when it seemed that the patient must drown in his own secretions, venesection cleared the bronchi and slowed respiration so that the patient was able to sleep. Blood was drawn with a needle into a sterile 8 ounce nursing bottle so that cultures might be made in each case. Out of forty cultures ten were found positive, showing pneumococcus Type I in 2 cases; Type II in 2 cases; Type IV in 4 cases, and *Streptococcus viridans* in 2 cases. Three patients having positive blood cultures recovered. Pfeiffer's bacillus was grown repeatedly from the sputum, lung puncture and necropsy material, but never from the blood stream.

---

* Owing to lack of space, this article is abbreviated in The Journal by the omission of several charts. The complete article appears in the authors' reprints.

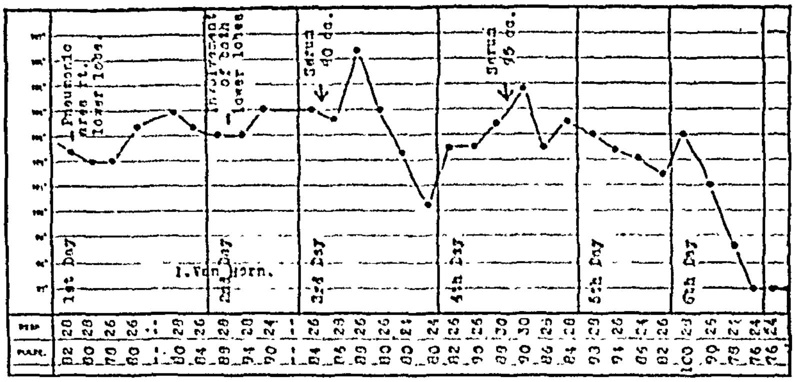

Chart 1.—Temperature, respiration and pulse in a case of influenzal pneumonia in a nurse. The attack began with a severe chill, cough, marked general pains, nausea and vomiting. Physical examination revealed signs of beginning pneumonia in the right lower lobe posteriorly. On the second day the pneumonic area in the right lower lobe showed signs of extending, and a small area was made out in the left lobe. The patient was prostrated, vomited continuously, and was unable to retain anything by mouth. She refused to accept serum treatment. On the third day the patient was much worse. Physical signs of pneumonia were extending in both lower lobes, prostration had increased, vomiting continued, and she was stuporous. Following the injection of plasma there was a chill with a rise in temperature to 106 with no disturbance in pulse or respiratory rate. Sweating was profuse. This was followed by a precipitate drop in temperature to 100 and an improvement of all symptoms. The patient was clear mentally, muscle pains were gone, and vomiting ceased. The following day the temperature again began to rise, the vomiting returned, and all subjective symptoms returned. A second injection of plasma was given and was followed by a slight chill and a rise in temperature. A few hours later the vomiting ceased entirely, the patient brightened up mentally, all pains were relieved, and convalescence was established.

At the height of the epidemic, a suggestion came from Boston Chelsea Hospital that the serum from convalescent patients might be of curative value. We at once determined to give the method[1] a thorough trial, but we chose to use citrated plasma rather than the serum obtained by clotting and centrifuging.

The apparatus and procedure as used by us has already been described.[2] Blood plasma is obtained by this method with the minimum of labor and danger of contamination. A larger amount of plasma is obtainable and the excess fluids added are a distinct advantage in view of the profuse perspiration following its administration. We believe that the failure of this method of treatment has been due in many cases to its having been tried half-heartedly, owing to the difficulties and labor involved in the collection of the plasma or serum.

On being discharged to the convalescent wards, the pneumonia patients are sent to the laboratory for Wassermann tests, and their venereal history is carefully inquired into. If convalescents are accepted, they are bled twice after being about the ward from four to six days, in amounts of from 300 to 500 c.c., with several days intervening between the bleedings. In only two instances have the donors mentioned sensations of faintness; these were of transient character and were probably due to the rapidity with which the blood was withdrawn. A majority of the men noticed that they gained weight much more rapidly after they had given blood.

The blood thus drawn is sedimented in the ice chest from twelve to twenty-four hours, and an average of 250 c.c. of plasma citrate-salt solution mixture are obtained from every 500 c.c. of blood.

METHOD OF ADMINISTRATION

The plasma is administered intravenously from a graduated container by the gravity method. A small needle and low pressure are used so that fifteen or twenty minutes are consumed in giving the average dose of 125 c.c. The arm selected is elevated and supported with a pillow, care being taken that there is no tight clothing about the shoulders, thus avoiding the possibility of stagnation and agglutination in the vein.

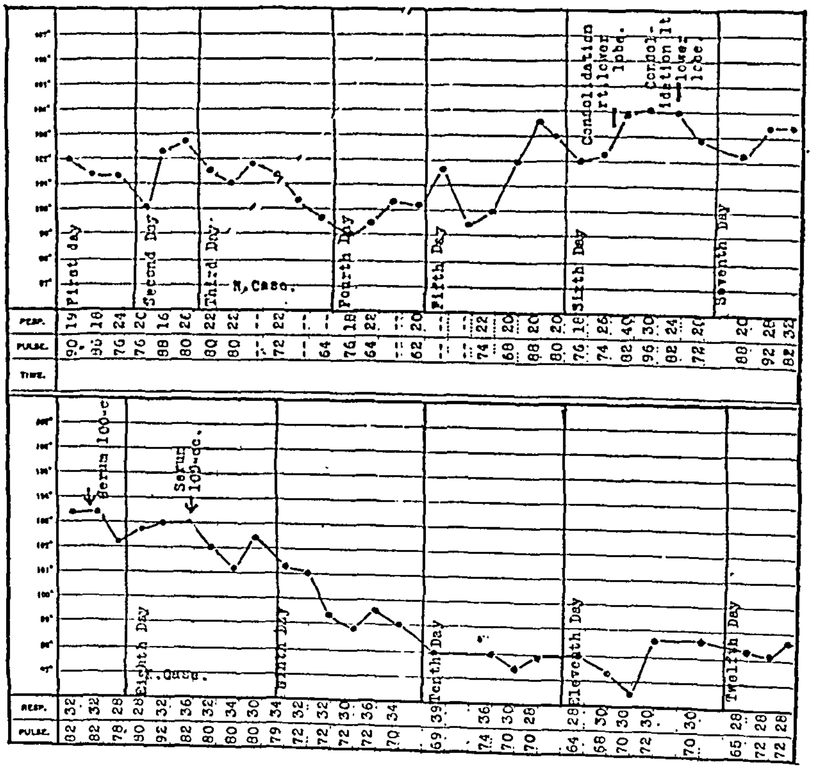

Chart 2.—Temperature, respiration and pulse in a case of influenzal pneumonia in a pharmacist who on the fifth day complained of being weak and worn out. No definite physical signs were made out. On the following day he was stuporous, showed marked prostration, and developed a severe cough. Physical examination revealed small pneumonic areas in both lower lobes. Twenty-four hours later he was given 100 c.c. of serum. There was no chill or reaction following it, but there was an immediate and marked improvement in his mental condition and entire relief from muscular pain. The injection was repeated on the following day and no reaction followed it. Next day the temperature reached normal.

With these precautions taken, it is not essential that the plasma be compatible with the blood of the patient. Indeed, grouping of the plasma and tests for compatibility are eliminated altogether. Doses of less than 100 c.c. are not indicated because they may produce uncomfortable reactions in the patients without giving any permanent relief of their symptoms.

---

[1] The details of the method were later published by McGuire, L. W., and Redden, W. R.: Treatment of Influenza Pneumonia by the Use of Convalescent Human Serum, J. A. M. A. **71:** 1311 (Oct. 19) 1918.

[2] Hartman, F. W.: New Methods for Blood Transfusion and Serum Therapy, J. A. M. A. **71:** 1658 (Nov. 16) 1918.

REACTIONS FOLLOWING ADMINISTRATION

In approximately 75 per cent. of the patients there is a response of some kind within two hours. This may be manifest by chilly sensations or a frank chill lasting several minutes, a rise in temperature of from 1 to 2 degrees, and drenching perspiration. The use of hot water bottles and extra blankets at this time affords comfort to the patient and encourages perspiration. In our experience these reactions do not weaken or prostrate the patient, but leave him with a slower pulse, freer and easier respirations, and a reduced if not a normal temperature. At the same time the subjective symptoms of headache, muscle pain and mental depression are relieved in a marked degree.

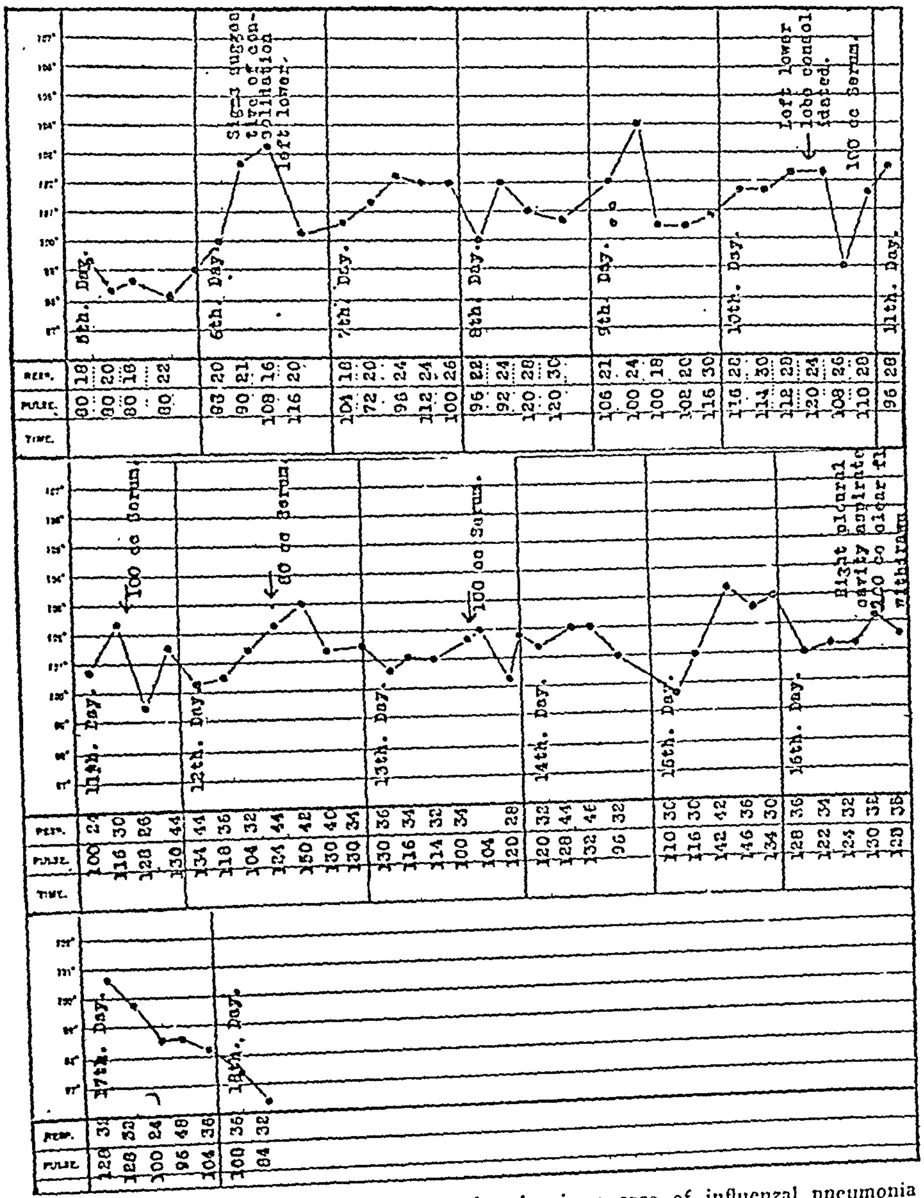

Chart 3.—Temperature, respiration and pulse in a case of influenzal pneumonia complicated by pleurisy with effusion.

Chart 1 is that of a nurse who refused the treatment until there was involvement of both lower lobes, and she was too ill to care what happened. In addition to other symptoms, she vomited constantly. Within two hours after she had received 80 c.c. of plasma, the temperature began to fall and the vomiting ceased. This relief lasted only eight hours, but a second injection (against which she was alert enough to protest strongly) was followed by cessation of vomiting and uneventful recovery.

One fourth of the cases show no reaction or only perspiration, yet get the same though perhaps less prompt results from treatment. Chart 2 is that of a pharmacist who would not give in to the infection until pneumonia developed, areas of consolidation were made out in both lower lobes, and the respiration rate was 32 per minute. Two doses were administered within a twelve-hour period. Almost immediately there was a complete change in the mental attitude and physical condition. At the end of twenty-four hours the temperature was normal. As expressed by the patient himself, a heavy weight seemed to be lifted off him in such a way as could only be appreciated by one who had experienced it. Again and again we have seen patients pass from the preliminary stage, after treatment, into sound sleep, like that of a child, to awake hours later feeling perfectly well, ready to eat anything.

Those pneumonias developing in the hospital and treated within forty-eight hours have shown the most clear-cut and striking results, due, we believe, to the neutralization of the toxin or toxins freeing natural forces to combat secondary invaders. In these cases the physical signs do not extend, but may persist for several days. In the terminal stages circulation is so poor and the lung involvement so extensive as to make this treatment uncertain and unsatisfactory because serious symptoms may be aggravated rather than relieved.

POTENCY OF PLASMA

In the first cases we injected only the compatible plasma; hence we were unable to pool that drawn from the various convalescents. With this procedure it was found that 25 per cent. of the plasma was very potent, 65 per cent. was moderately potent, and 10 per cent. was inactive. The plasma collected as late as thirty days after the temperature had become normal seems to be potent, as is also that of convalescents who were treated during their pneumonia.

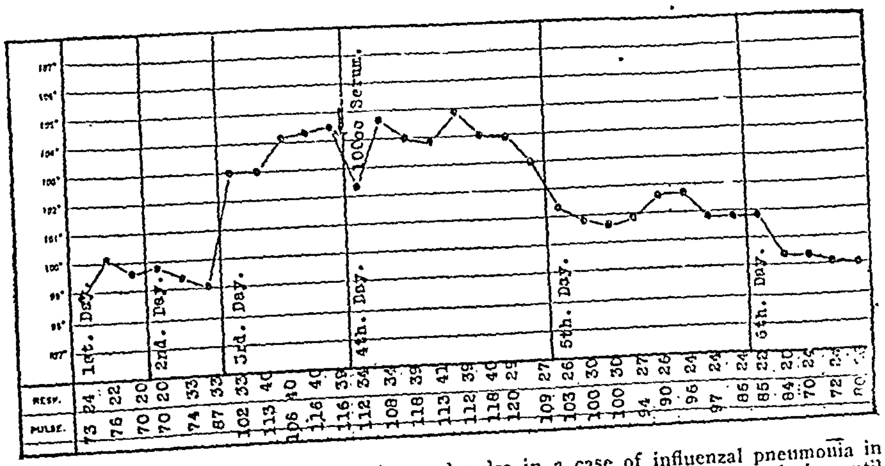

Chart 4.—Temperature, respiration and pulse in a case of influenzal pneumonia in a woman who was a superintendent of nurses and refused to give up her duties until prostrated. On the third day the temperature rose to 103, pulse 113, and respirations 40. Signs of pneumonic areas in the lower lobes of both lungs were made out. One hundred c.c. of serum were administered intramuscularly. During the next twenty-four hours the temperature fluctuated between 104 and 105, and then began falling by lysis, accompanied by improvement in both pulse and respiration. The patient was discharged on the twelfth day.

Agglutination and complement fixation tests with five strains of the influenza bacillus and twelve different serums were uniformly negative. Agglutination tests on Types I, II and III pneumococci were likewise negative. Unfortunately no such tests were made with the diplostreptococcus, which was present in many of the early cases.

RESULTS OF TREATMENT

Complications of any kind interfere markedly with recovery. Pleurisy, and particularly pleurisy with effusion, seems to neutralize the beneficial properties of the plasma. Chart 3 is that of a patient first treated five days after suggestive signs of pneumonia were made out. Each of four injections was followed by temporary improvement, but he grew weaker until the sixteenth day, when, following the aspiration of 200 c.c. of fluid from his right pleural cavity, the temperature dropped to normal and an uneventful recovery was made.

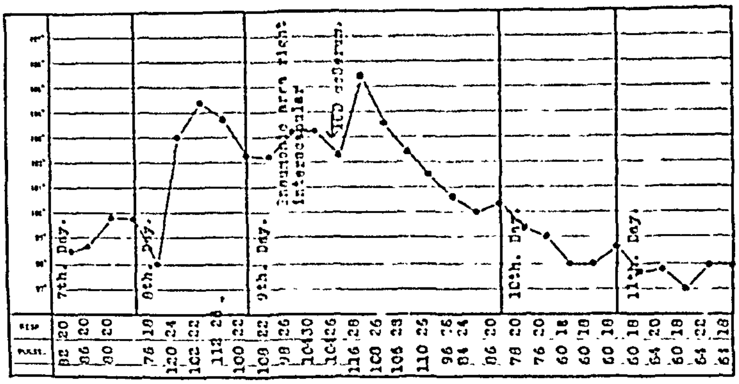

Chart 5.—Temperature, respiration and pulse in a case of influenzal pneumonia developing five days after temperature became normal.

Two of three fatal cases showed extensive fibrinous pleurisy with an effusion of about 200 c.c. of serosanguineous fluid, containing many pneumococci in each pleural cavity. The third case showed an encapsulated empyema on the left side from which Group I pneumococci were cultivated. One of the two patients mentioned above had a pneumococcus Type IV septicemia, the organism producing green coloration in different culture mediums. Treatment in all three cases was begun late, either because we did not see the cases until late or because definite signs of pneumonia were not made out until late.

Up to the present time, forty-six cases of influenzal pneumonia have been treated with three deaths resulting, making the mortality percentage 6.5. Of 111 patients untreated, twenty-eight died, giving a mortality percentage of 25.2, or about four times the percentage mortality among forty-six treated cases.

CONCLUSIONS

1. The toxemia of influenza seems to be neutralized by the plasma from convalescent patients.

2. Certain care being exercised, tests for compatibility are eliminated.

3. A large percentage of all plasma is active, and most satisfactory results are obtained by pooling the different lots.

4. Sharp reactions are followed by the most prompt improvement, but are not essential to success.

5. Pneumonia must be diagnosed early and treated immediately if a large percentage of recoveries are to be obtained.

OPERATIVE TREATMENT OF GUNSHOT WOUNDS OF THE SPINE WITH GRAVE PARALYSES *

HAROLD NEUHOF, M.D. (New York)
FRANCE

It appears to be generally held that operation is contraindicated in recent gunshot wounds of the spine when there is complete or almost complete paralysis and sensory loss below the level of the cord injury. From a number of reported observations, however, it seems clear that paralysis ranging from slight to most extreme may be associated with wounds in the neighborhood of the spine without involvement either of bone or of dura. The hopeless destruction of the cord by the missile or by bone fragments can be determined without operative intervention in not a few cases, and in these operation is of no avail. There are many cases, on the other hand, in which such cord destruction cannot be shown unequivocally by roentgenographic and clinical examination and the study of the course of the missile, instances in which operation may reveal a partially severed, contused or compressed cord. Basing my opinion on several experiences with cases of this type, I believe that these patients should be given the benefit of doubt as to the completeness of the cord lesion, and that operation should be performed in the hope of encountering remediable conditions.

My special purpose in the present contribution is to discuss a group of cases of gunshot wound of the spine in which the dura is intact in the presence of complete or almost complete paralysis, the lesion in the cord being attributable to commotion or concussion or to both combined. In the fatal cases examination discloses either a diffuse or a focal necrosis in the affected part of the cord with a varying degree of surrounding edema. Sometimes all the cord elements are destroyed at this level, but more frequently greater or lesser portions remain intact. The presumption is that in the favorable cases, those in which functional recovery occurs to a varying degree, edema was a prominent element in the lesion. There is, then, a group of cases of gunshot wounds in the spinal region, with intact dura and with grave paralysis, in which the possibility of return of function exists. In injuries by shell fragments, the chances of recovery from the wound are greatly reduced or even entirely eliminated if a deep-seated wound infection is added to the cord lesion with its complications. In addition to the indirect effect on the cord of the type of injury in question, there may be fragments of bone or epidural clots directly compromising the dura, the removal of which would aid in recovery and reduce the likelihood of epidural infection. It is chiefly, however, for the elimination of infection, and not with the expectation of relieving pressure on the cord, that I believe prompt operation is indicated in these cases. This point of view received support in a series of spinal wounds under my care at British Casualty Clearing Station No. 17 last year. Of twenty-two patients with spinal wounds accompanied by manifestations of severe damage to the cord, four fell into the category of

---

* From Mobile Hospital No. 2, A. E. F.

wounds with complete or almost complete paralysis and intact dura. Operations were performed within short periods of the time the wounds were inflicted. The subsequent course was satisfactory in all four cases. This cannot be ascribed to the operation on the spine in itself, but to the control or elimination of infection.

Concerning the technic of operation that was employed, little need be added to the details given in the case reports. The wounds were excised in the usual manner. When the roentgenographic examination showed fracture of the spines or laminae, or when an intradural hemorrhage was suspected, laminectomy was done. This was carried out in the typical way rather than by a piecemeal removal of loose or detached fragments of bone. I believe that the latter procedure, in the necessarily limited operative exposure and the distortion of landmarks, may inflict damage to the dura and possibly to the underlying cord. The dura was not opened in any of the cases in question, because there were no visible signs of a subdural lesion. After recent injuries, patients with serious cord damage are not good operative risks, and the operation should, therefore, be expeditiously performed; suitable instruments are important aids to this end.

The following are reports of the four cases of gunshot wounds of the spine in which paralysis was complete or almost complete, and in which the dura was found to be intact. The spinal column was fractured in three, but in only one of these was there any indication of direct pressure on the dura. There was no demonstrable bone injury in the fourth case. The follow-up notes are included in the case reports.

REPORT OF CASES

Case 1.—*Penetrating wound in the cervical region, with missile lodged between atlas and axis. Almost complete quadriplegia. Excision of tract and removal of foreign body. Progressive improvement.*

The patient, admitted, October 24, sixteen hours after being wounded, complained of loss of power in all four extremities, was unable to void, and had severe pain in both arms. The entry wound was a large, lacerated one in the left suprascapular region. There was profound weakness of both arms, the left being almost completely paralyzed; there was double wrist drop. All reflexes were absent except the right triceps. The abdominal reflexes were absent, the cremasterics sluggish. There was marked paresis of the right leg, almost complete paralysis of the left, double foot drop, and slight knee and ankle jerks. Detailed sensory examination was impossible because of the patient's restlessness and poor general condition; however, there appeared to be complete sensory loss up to the level of the fourth dorsal segment, and reduction in sensation from there to the third cervical. Roentgenographic examination revealed a large foreign body to the right of the midline and immediately above the body of the second cervical vertebra.

Operation, performed shortly after admission, consisted in excision of the entrance wound and tract. This crossed the midline above the third cervical spine without producing any bone injury. The tract ran deeply alongside the spinous process of the axis up to the foreign body lodged between the arch of the atlas and the body of the axis. The posterior atlanto-axial ligament was divided on the right side, but there was no evidence of epidural clot. The foreign body was removed and the wound sutured.

During the week's postoperative observation there was progressive improvement and power on the right side, slight on the left, and reduction of sensory disturbances; there was incomplete bladder control. A medical report three weeks later stated that the power was good in both legs and the right arm, and that movements were returning to the left arm; there were no areas of complete sensory loss; the bladder control was fair.

Subsequent reports described progressive improvement. The last report, eight months after operation, states that there is good power in both legs, the patient being able to walk short distances without assistance; the power in the right arm is almost normal, and the left arm is steadily improving; there is full control of bladder and bowels.

Case 2.—*Perforating wound of neck with fractures of spines and laminae of fifth and sixth vertebrae. Almost complete quadriplegia. Excision of tract, and laminectomy. Progressive improvement.*

The patient, admitted, November 8, forty-eight hours after being wounded, had been unconscious for about eighteen hours; he then found that his legs were paralyzed, his arms numb and weak, and that he was unable to void. The entrance wound was a small one in the left suprascapular region, the exit a large, ragged one in the right suprascapular fossa. There were slight movements at the left shoulder, slight flexion at the elbow, no extension, and complete wrist drop. Except for very slight rotation at the shoulder and flexion at the elbow, there were no movements in the right arm. The abdominal and cremasteric reflexes were absent. The right leg was completely paralyzed, and this was true for the left leg except for slight flexion and extension at the hip. The knee and ankle jerks were absent. Sensations were reduced from the fifth cervical to second dorsal segments, and lost from the latter level downward. Roentgenographic examination revealed a fracture of the body and laminae of the fifth cervical vertebra without in-driven fragments.

Operation, performed shortly after admission, consisted in a typical laminectomy. After separation of musculature through a median incision, the spinous processes of the fourth, fifth (fractured) and sixth cervical vertebrae were stripped free and removed. This was followed by removal of the corresponding laminae; there was considerable comminution of those of the fifth, and less of the sixth. None of the fragments impinged on the dura. This was found intact, of normal color, and without any suggestion of subdural injury. The tract was excised, the laminectomy wound closed, and the sites of entrance and exit drained.

Improvement occurred in the eight days' hospital observation. At the time of discharge there was partial bladder and good bowel control. Sensation had largely returned except over areas on both legs. There was fair motion and power at the left shoulder and elbow, and incomplete wrist drop; total right-sided wrist drop persisted, and the motions at the right elbow and shoulder were still very slight. All motions were present in the lower extremities, although to a very slight degree on the right side. The abdominal reflexes were sluggish, the cremasterics absent. Knee and ankle jerks, bilateral ankle clonus and the Babinski phenomenon were present. The laminectomy wound healed by primary union; the drained wounds were in satisfactory condition.

Reports on the subsequent course were received from the patient. There have been several setbacks, but improvement has been progressive. The last report, nine months after operation, describes tentative efforts at walking, good power but considerable stiffness in the legs, good power in the left arm, and fair power in the right.

Case 3.—*Penetrating wound of dorsal spine with missile lodged in thorax. Almost complete paraplegia. Laminectomy and partial excision of tract. Progressive improvement.*

The patient, admitted, November 12, seven hours after being wounded, had immediate paralysis and numbness of the legs following the injury, and was unable to void. There was a small lacerated entrance wound over the seventh dorsal spinous process. The general condition was poor. There were physical signs of a left-sided hemothorax, and profound paresis of both legs, more so on the left side, where there was very slight motion at the hip and knee, with none at the ankle and toes. Knee and ankle reflexes were present. Sensory disturbances of a somewhat Brown-Séquard character began at the level of the ninth dorsal segment. Roentgenographic examination revealed fluid in the left pleural cavity, and a small shell fragment to the left of the body of the eighth dorsal vertebra.

Operation was performed six hours after admission, when the general condition had somewhat improved. The entrance wound was excised, and a typical laminectomy performed. The spines and laminae of the seventh, eighth and ninth dorsal vertebrae were removed. There was a comminuted fracture of the left transverse process and lamina of the eighth, some of the loose fragments impinging on the dura. A small epidural clot was removed. Excision of the tract to the pleura was performed, further intrathoracic dissection being considered inadvisable owing to the general condition of the patient and the type of operative exposure required for access to the foreign body in this region. The wound was sutured in layers.

In the ten days' postoperative observation at the hospital, the wound healed by primary union, and complete bladder control returned. There was steady improvement in power and range of motion in the right lower extremity; there were slight motions at the left hip and knee, but none at the ankle or toes. There was reduction in the area of altered sensation.

Progressive improvement was reported from time to time. Five months after operation the patient was up and about with good power in the right leg and fair power in the left. The last report, seven months after operation, states that, except for slight weakness in the left leg, there is normal function in both legs.

Although it was an injury to the cauda equina, the following case is included because it presents the same picture of central injury with intact dura:

Case 4.—*Penetrating wound in lumbar region with missile lodged in front of vertebra. Paralysis of right leg. Laminectomy and excision of tract. Progressive improvement.*

The patient, admitted, October 19, six hours after being wounded, with loss of power in the legs, inability to void, and severe, shooting pains down the right thigh and the leg, had received a large, ragged wound in the right lumbar region. In the right leg slight motion was present at the knee and absent elsewhere; on the left side slight motions were present at the hip, knee and ankle. Both knee jerks were absent; the left ankle jerk was present, the right absent. All sensations were lost in the distribution of the fourth and fifth lumbar and first sacral roots. Roentgenographic examination revealed a large shell fragment anterior to the body of the third lumbar vertebra.

The first stage in the operation consisted in laminectomy, because it was thought from the roentgenographic examination that the foreign body had traversed the laminae. The third, fourth and fifth lumbar spines and laminae were removed, without any fracture being disclosed. The tract of the missile was then excised. The tract was found to pass through the body of the third lumbar vertebra. Loose bone fragments were removed; the foreign body could not be felt. The laminectomy wound was closed, and the remainder of the wound treated by Carrell-Dakin's method.

There was postoperative pneumonia. On examination from the hospital, ten days after operation, power in the left lower extremity was greatly improved; slight motions were present at all the joints of the right. There was improvement in sensation.

Discharge from the wound continued for several weeks, ceasing after removal of the foreign body and some bone fragments. Four months after operation the patient was able to walk with the aid of a cane, the left leg was normal, and power was much improved in the right. No subsequent report has been received.

Infant Breast Feeding.—It is of paramount importance to the future of this country that infant breast feeding should be maintained and extended. There must be no avoidable spilling of infant life. Every little stranger is now no longer a somewhat unwelcome intruder, but a precious commodity to be jealously guarded.—Sir James Crichton-Browne, *Journal of State Medicine,* May, 1918.

RÔLE OF THE BLOOD AND THE BONE MARROW IN CERTAIN FORMS OF GAS POISONING

I. PERIPHERAL BLOOD CHANGES AND THEIR SIGNIFICANCE

E. B. KRUMBHAAR, M.D. (Philadelphia)
Captain, M. R. C., U. S. Army
FRANCE

Hematologic examinations made during the past ten months in a base hospital in France on certain gassed patients (mustard gas) offer strong evidence that the deleterious action of the poison on the blood and bone marrow is an important factor in prognosis in many cases.

The first change in the circulating blood—apparently due to a stimulus to the bone marrow—is an increase in the erythrocyte and leukocyte count, that naturally varies greatly with the severity of the gassing and the individual's reactive powers. In view of the disproportionate increase of red and white cells, change in Arneth scale, etc., the possibility of this being due to a greater concentration of the blood may safely be disregarded. The leukocyte rise (due to the polymorphonuclear elements) may be as high as 36,000 per cubic millimeter, and in the present series averaged 12,000. Enumeration of the lobes of the nuclei (Arneth count) shows at this time a shift of the Arneth scale to the left, that is, young polymorphonuclears are entering the blood stream. This increase of leukocytes soon disappears in the slightly gassed patients, the count gradually returning to normal, and in the severely gassed patients falling rapidly. The shift of the Arneth scale to the right at this period indicates an exhaustion of the leukocyte-forming centers. If death does not interrupt the downward course, an extreme degree of leukopenia (at the expense of the polymorphonuclears) may be reached. Thus the leukocyte counts of four fatal cases were observed to fall steadily from (1) 10,200 to 2,900; (2) 17,800 to 3,200; (3) 20,400 to 7,600, and (4) 36,000 to 14,000 per cubic millimeter. Postmortem examination of the femoral bone marrow reveals only a slight mottling, shown histologically to be due to primordial cells and megaloblasts, with a greater or less disappearance of normoblasts, myelocytes and adult forms. This has been interpreted as an inadequate attempt at blood regeneration, and the resulting lack of leukocytes in the blood stream may be considered to amount to an important weakening of the body defenses. Even in the bronchopneumonia that frequently supervenes in severely gassed patients, little or no reactive rise in leukocyte count is observed. In the accompanying table, only those cases are credited with bronchopneumonia, in which it was found at necropsy, and yet there are in it several instances in which leukopenia coincided with extensive bronchopneumonia. It is recognized, of course, that death may occur while moderate leukocytosis still exists; but a high leukocyte count should undoubtedly be considered a favorable item in the prognosis of a serious case of gassing.

In two cases of especial interest, leukocyte counts taken nine days after gassing showed the extraordinarily low counts of 570 (Harden) and 520 cells per cubic millimeter (Kerr), chiefly due to an almost total disappearance of polymorphonuclears. Both patients in ensuing daily counts showed a progressive rise with outpouring of myelocytes into the blood stream, but died with an extensive bronchopneumonia before the blood picture returned to normal. This may be interpreted as a partial recovery of the bone marrow from the initial insult, but not in time to help adequately to protect from the bronchopneumonia.

The question as to whether there is a real loss of leukocytes or a redistribution in the lungs at the expense of the blood stream must be taken into consideration, especially in view of the experimental work of Edkins and Tweedy[1] on gassed rabbits. The bronchopneumonic lungs and inflamed tubes have certainly shown the masses of leukocytes that are usually found in these conditions, so that, especially in view of the changes found in the bone marrow, the most probable hypothesis to explain the leukopenia in the blood stream would seem to be that the damaged source of supply was unable to furnish sufficient leukocytes for the local needs, and as well a superabundance in the blood, as it normally is able to do. In this connection also the myriads of organisms and relative lack of pus cells in the sputum is of interest.

The changes in the other elements of the blood are less striking; the initial rise in erythrocytes is later replaced by a moderate anemia (occasionally reaching below 4 millions). That this is due to lessened blood formation, rather than increased destruction, is shown by the normal condition of the plasma, absence of choluria, and of poikilocytes or blast cells in the blood stream.[2] In convalescent cases, the increased blood regeneration is shown by a distinct increase in the number of skeined cells, as well as the return of the leukocyte count to or slightly above normal. In the earlier stages at least the coagulation time of the blood is decreased and platelets appear very numerous and large on a film, though no actual counts have been made. In the later leukopenic stage, the platelets are much sparser, and in one case a coagulation time of seven minutes has been noted.

Attempts to apply this theory of damaged blood and bone marrow to the treatment of gassed patients have

* 100 counts.

so far not seemed practical. The so-called bone marrow simulants would hardly seem apropos, with the factory out of gear and an intense stimulus probably already being furnished from the respiratory tract. Blood transfusions or leukocytic injections are impracticable on any extensive scale, and the preparation of extracts of animal leukocytes has not been possible. Any method of treatment, however, that would give promise of replenishing some of the lost protective power of leukocytes would seem well worth trial.

SUMMARY

1. Certain forms of gas poisoning cause, after an initial leukocytosis, a more or less extreme degree of leukopenia.

2. This usually persists even in the presence of bronchopneumonia and is very probably an important contributing factor to the high mortality of severe cases.

3. If the leukocyte count falls below 1,000 per cubic millimeter, a "myelocyte crisis" may bring about a partial amelioration; but in the two cases observed of this kind, this did not serve to protect from a fatal outcome.

4. Lessened blood formation is also indicated by the production of anemia without blast cell formation and diminution in the number of blood platelets. In the earlier stages the coagulation time is decreased, and in the later stages of severe cases it is increased.

Barbed Wire Disease.—Vischer (*Cor.-Bl. f. schweiz. Aerzte*, Sept. 28, 1918) has described a peculiar psychosis of war prisoners in all camps, including those interned as civilian aliens. The prisoners themselves have coined the term "barbed wire disease" for this trouble, and to those affected it is said the barbed wire within which they are inclosed acts as a red rag to a bull. At first after internment there are peculiar reactions due to shutting off of the outside world and mingling in close communion. The phase is one of stimulation. Men argue, become quarrelsome and envious, egosim is fostered. There is a rage for games. Gradually the picture changes to one of depression. Especially among the more finely organized, a state of apathy develops. One is no longer able to concentrate on anything. Even music becomes undesirable. The mental state resembles in some ways the so-called cafardism which was first noted before the war in the French foreign legionaries, and thus perhaps light is thrown on the motivation of that mysterious affection. Sleep is disturbed by dreams and there is an abnormal sensitiveness to sounds. Only a small percentage remain immune. The barbed wire acts throughout as the badge and symbol of servitude. The part played by the wire appears to be shown by the fact that prisoners who work in small squads in the open under guard do not develop the disease.

disappearance of polymorphonuclears. Both patients in ensuing daily counts showed a progressive rise with outpouring of myelocytes into the blood stream, but died with an extensive bronchopneumonia before the blood picture returned to normal. This may be interpreted as a partial recovery of the bone marrow from the initial insult, but not in time to help adequately to protect from the bronchopneumonia.

The question as to whether there is a real loss of leukocytes or a redistribution in the lungs at the expense of the blood stream must be taken into consideration, especially in view of the experimental work of Edkins and Tweedy[1] on gassed rabbits. The bronchopneumonic lungs and inflamed tubes have certainly shown the masses of leukocytes that are usually found in these conditions, so that, especially in view of the changes found in the bone marrow, the most probable hypothesis to explain the leukopenia in the blood stream would seem to be that the damaged source of supply was unable to furnish sufficient leukocytes for the local needs, and as well a superabundance in the blood, as it normally is able to do. In this connection also the myriads of organisms and relative lack of pus cells in the sputum is of interest.

The changes in the other elements of the blood are less striking; the initial rise in erythrocytes is later replaced by a moderate anemia (occasionally reaching below 4 millions). That this is due to lessened blood formation, rather than increased destruction, is shown by the normal condition of the plasma, absence of choluria, and of poikilocytes or blast cells in the blood stream.[2] In convalescent cases, the increased blood regeneration is shown by a distinct increase in the number of skeined cells, as well as the return of the leukocyte count to or slightly above normal. In the earlier stages at least the coagulation time of the blood is decreased and platelets appear very numerous and large on a film, though no actual counts have been made. In the later leukopenic stage, the platelets are much sparser, and in one case a coagulation time of seven minutes has been noted.

Attempts to apply this theory of damaged blood and bone marrow to the treatment of gassed patients have

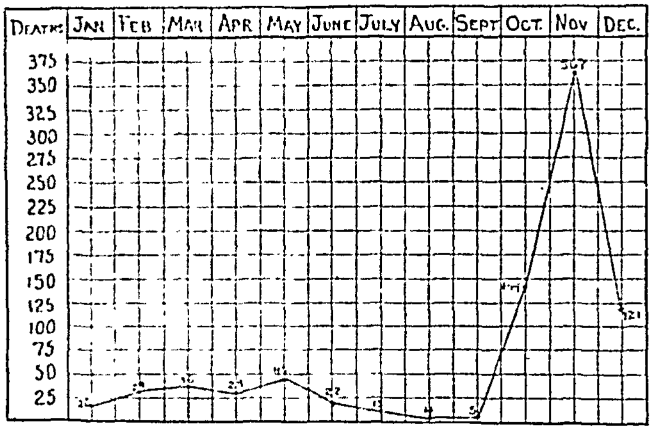
[2] Pearce, R. M.; Krumbhaar, E. B., and Frazier, C. H.: The Spleen and Anaemia, Philadelphia, J. B. Lippincott Company, 1918.

myocarditis, homicide, anemia and dilatation of the heart, each 15; cirrhosis of liver, 14; kidney disease (unclassified), 13; gastritis, 11, and many other diseases less than 10.

Influenza-Pneumonia.—The most notable factor in the deaths of the year is the enormous increase in deaths from pneumonia, and especially from those from pneumonia following influenza. During the years from 1902 to 1917, inclusive, the percentage of deaths from pneumonia to the total deaths varied from 5.62, the low mark, in 1914, to 9.47, the high mark, in 1916. With the opening of the year 1918, however, there was an increase in the deaths from pneumonia, so that for the first nine months of the year the percentage was 12.5. The enormous increase occurred in the last three months of the year, which brought the percentage of deaths from pneumonia and influenza for 1918 up to 30.69, an unprecedented mortality.

Accident.—The causes assigned for the 89 deaths from accident were: automobile, 24; automobile-railway (grade crossing), 16; falls, 10; railway, 8; poison, 4; in conflagrations, drowning, sunstroke and unclassified accidents, each 3; burns, injuries by animals and explosion, each 2; and roentgen-ray burns, inhalation of poisonous gases, fracture, freezing, lightning, starvation, firearms, injuries in mine, crushing and asphyxia, each one. The 39 physicians who ended their lives by suicide selected the following methods: firearms, 20; poison and cutting instruments, each 6; strangulation, 3; asphyxia, drowning, jumping from high places, and unclassified, each 1. Of the 15 homicides, 11 were due to firearms; 3 to causes not stated, and one was due to cutting instruments.



Deaths of physicians from influenza and pneumonia during 1918.

Military Service.—During the year, one physician died who had served in the Mexican War; 165 were veterans of the Civil War, and of these, 37 had followed the fortunes of the Confederacy, and 44 had been medical officers of United States Volunteers. The Medical Corps of the Army lost 253 officers; 13 had been contract or acting assistant surgeons. The Navy lost 35 medical officers and 4 acting assistant surgeons; the Public Health Service, 10; the Indian Service, 5, and the organized militia, 33, of whom 5 had attained the grade of Surgeon-General.

Civil Positions.—Of those who died, 2 had been members of Congress; one, an ambassador; 2, consuls; 4, members of state senates; 24, members of the lower houses of legislatures; and 33 had been mayors; 20 had been members of state boards of health; 10 of state boards of medical examiners, and 7 members of other state boards.

Association Fellowship.—Of the 994 Fellows of the American Medical Association who died during 1918, one had been Vice President; one, a member of the House of Delegates; 2, members of the Committee on Medical Legislation; one, a member of the Judicial Council; 5, section officers, and one a member of the Board of Trustees.

THE HEALTH OF THE ARMY

The report of the Surgeon-General of the Army covering the calendar year of 1917 and the fiscal year to June 30, 1918, has just appeared. Naturally it is a much larger volume than any previous report. It is divided into eight sections with some 181 general tables, twenty-one special tables, ten international tables and seventy-three charts. This is a compilation of data which required great effort and adequate organization. In the letter of transmittal, special attention is called to the three training schools for medical officers which aided in rapidly building up an efficient medical department for the great army created by the war. The health of the Army both at home and overseas was excellent, and the death rates probably lower than in any other similar body of troops in the history of warfare. As an evidence of the way in which typhoid fever has been eliminated from the Army, it is stated that there were 297 cases and twenty-three deaths during the year 1917. If the morbidity had been as great as during the Spanish-American War, there would have been 136,000 cases and 13,600 deaths. It was seen before the troops had been mobilized that the acute respiratory diseases would be the greatest factors in morbidity and mortality, and every possible effort was made to prevent their incidence. The rapid mobilization, however, made it impossible to secure the desired results. Pneumonia, either primary or secondary, caused approximately 65 per cent. of the deaths from all causes in the troops in the United States in 1917. A large number of the pneumonias have been charged to measles, which was epidemic during that year.

The second section is a comparative study of the health of our army from 1820 through 1917. This includes a comprehensive analysis of the health of the Army according to race, location, age, length of service and rank, and a good analysis of the causes of death. It is interesting to note that in 1916 there were twenty-two causes of death, and in 1917 only eight, each of which produced at least 1 per cent. of all the deaths of the year. Of the eight leading causes of death in 1917, five are of an epidemic character, and measles is the most important. In 1916, measles is eleventh on the list of causes of death, that is, 3.3 per cent., as contrasted with first place and 29.9 per cent. in 1917. Most of the deaths from measles were, of course, from the complicating pneumonia.

A large section of the book is concerned with the mobilization of the Army. Our readers are already familiar with the tremendous growth of the Medical Department. Today this department alone is larger than was the entire army at the outbreak of the Spanish-American War. In this section is included a description of each of the great camps and cantonments, with a discussion as to health conditions and the factors especially related to those camps. Here also is described the organization of the base hospitals in the cantonments. The fourth section concerns the health of the Army by countries in which different units were located, and the fifth section, special diseases in the Army, with numerous charts showing how measles, the pneumonias, venereal diseases and other infections were brought under control. A special section is devoted to a consideration of fractures.

The sixth section, on the activities of the Medical Department, describes in detail the organization and the work of each department of the Army, including the handling of infectious diseases, sanitation and construction of hospitals, the work of the gas division, the work of the Army medical laboratory, and the special divisions in the Surgeon-General's Office. Section H is the financial report, showing how more than $100,000,000 was spent.

To those who have been interested in tracing the development of the Medical Department and the great service it has rendered to the government, the report will be an interesting and enlightening document. It should be of permanent value to hygienists, sanitarians and to others interested in the control of disease.

PROPHYLACTIC INOCULATION AGAINST INFLUENZA

Experiment is the life of natural science. The primary condition of progress is that one must be eternally questioning, testing, trying out new ideas and methods—in the old-fashioned phrase, "interrogating Nature." The successful investigator ceaselessly observes, theorizes and formulates experiments to verify his hypotheses. To experiment is of the essence of our faith.

As investigators know, however, it is not easy to plan and conduct an experiment in such a way that the results are unambiguous. Even in the purely physical sciences the elimination of all factors except the one whose action we wish to study is not always a simple matter. In the biologic sciences and especially in human medicine, conditions are usually so complex and the multiplicity of factors so great that the study of any particular factor is often fraught with great difficulty. Any one familiar with the history of the numerous attempts made in the past twenty years to use specific and nonspecific serums and vaccines knows of the countless wrecks of well meant endeavor and patient industry that lie high, dry and forgotten on the rocks of fact. No one of us believes for a moment that on this account we should slacken our effort or abate our enthusiasm. The success already achieved in the prophylaxis and treatment of several infectious diseases is enough to spur us on to fresh trials and new modes of experiment.

At the same time we have a right to ask that experiments in this field, where so much is at stake, where our hold on the confidence of the general public is involved, and where self deception is peculiarly liable to occur, be planned and carried out with as much precision and critical acumen as possible, so that proper conclusions may be drawn and the whole matter not left fogged with uncertainty. The trouble with so much of the "evidence" on the use of vaccines for the prevention of influenza—as stated in the recent report of the Committee of the American Public Health Association—is not that it is "contradictory and irreconcilable," but that it is not evidence at all; the pertinent facts are not collected and evaluated in such a way as to constitute solid grounds for either a favorable or unfavorable opinion. That is the real reason why confusion and uncertainty today surround much of the reported work on the prophylactic inoculation against influenza: the data presented are simply too inadequate to permit a competent judgment.

To what extent these considerations apply to an important article[1] presented in The Journal this week must be decided by each reader for himself. It may be questioned, perhaps, whether the greater receptivity for positive rather than negative results shown in the phrase, "because, after all, the results from prophylactic inoculation must be sufficiently favorable to be apparent under the conditions included in this report," is justified in an inquiry demanding such a rigorously critical attitude as the one in hand. Positive results are certainly more gratifying to the average investigator than negative; all the more reason, therefore, why he should hold himself a little stiffly and be ever on his guard against an uncritical acceptance of a desired fact.

To be more specific, one could wish that definite statements might be made in place of vague and general statements, that the readers might be taken more fully into the confidence of the writer with respect to seeing for themselves those data on which he bases his conclusions. When we read: "This difference has been noted in communities in which the incidence and mortality rate were exceptionally high as well as where they were comparatively low," we want to ask: What were the communities and what was the population, what the incidence and what the mortality rate; where and to how many was the vaccine given, and what were actually the results?

---

[1] Rosenow, E. C.: *Prophylactic Inoculation Against Respiratory Infections*, this issue, p. 31.

It is not quite clear from Rosenow's article just what his position really is with respect to the effect of his vaccine in warding off initial attacks of influenza. Although, at the beginning of the paper, he seems to regard the vaccine as a means of increasing individual resistance to the secondary infections that follow in the wake of the primary influenza, later on, as in referring to the State Hospital for the Insane at Rochester, he attributes to it the virtue of preventing the primary infection.

There are other points of detail about which the curious reader will want further information. He will want to know dates, places, ages and population inoculated and uninoculated; he will want to know something about the clinical basis of diagnosis, the proportion of pneumonias, the conditions of exposure, and especially the measures taken to prevent influenza infection and to prevent the development of pneumonia in each group chosen. To specify only one case: The experience at a Rochester hospital—where fourteen nurses (out of how many?) developed influenza within two days (how many earlier?) prior to the first inoculation (at what period in the epidemic?), and only one case (out of how many possibilities?) developed subsequently during a period of six weeks—might be duplicated, so far as the facts given are concerned, in the experience of other observers using no vaccines whatever. In other words, unless all the cards are on the table, unless we know so far as possible all the factors that may conceivably influence the results, we cannot have a satisfactory basis for determining whether or not the results of prophylactic inoculation against influenza justify the interpretation they have received in some quarters.

A Municipal Poultry Farm.—The health committee of the city of Bradford, England, according to U. S. Consul A. E. Ingram (*Commerce Reports,* Jan. 15, 1918), in May, 1916, established a municipal poultry farm to meet the demands of the hospitals and other medical institutions maintained by the municipality. It is situated on the farm of the Bierley Hall Sanatorium for consumptives, covers 6 acres and comprises about fifty buildings, with 800 birds of the standard egg breeds, and is fully equipped for poultry and egg producing purposes according to the latest scientific ideas. The surplus accumulations of eggs are preserved by the waterglass process. The initial outlay was about $10,000, and it is found that the cost of running the plant will amount to about the same sum annually. It is expected that the egg production will reach 80,000 a year.

Current Comment

"EVIDENCE"

> "I have used between 700 and 800 doses of The Cutter Laboratory's Mixed Vaccine-Respiratory Infections as a prophylactic against Influenza, and in not one instance has there been a failure completely to protect the individuals so immunized."

This testimonial heads a postal card distributed widely to physicians by the Cutter Laboratory, which claims that the statement is "by one of San Francisco's best known physicians." The Cutter Laboratory is of the opinion that the statement "is convincing enough to satisfy even the most conservative as to the value of Mixed Vaccine prophylaxis in this class of infections." Let us extend the method of argument:

> "I have recomended to 643 of my patients that, as a prophylactic against *Influenza, they use a teaspoonful of salt instead* of two lumps of sugar in their coffee every morning, and in not one instance has one of these patients come down with the disease."

Then might not the salt producers of the country say that the statement just given, having supposititiously come from one of New York's best-known physicians, is convincing enough to satisfy even the most conservative as to the value of sodium chlorid as a prophylactic in influenza? The science of therapeutics is complex enough at its best. With commercialism dominating the production of therapeutic agents, the likelihood of ever arriving at anything even approximating a true science of therapeutics seems hopeless. If there were as much money to be made in astronomy as there is in pharmacy, there would be a new star discovered every day.

AUTOTOXEMIA

Few physicians ever question the ancient therapeutic axiom, "Bene curat qui bene laxat." The administration of a laxative or cathartic at the onset of an illness constitutes the chief hope of the layman and the auxiliary measure of the physician in effecting a rapid cure. This is based on the assumption that opening up the chief emunctory of the body sweeps out the poisonous products ingested or formed by action of the intestinal flora on nitrogenous food, preventing them from exerting their toxic action on the various organs and tissues of the body. That the symptoms of intestinal stasis and constipation are those of an intoxication or autotoxemia resulting from an absorption from the intestinal tract of the poisonous products of bacterial activity is supposedly so well established as a clinical fact that a host of medicinal agents have been exploited for its relief and several surgical procedures have been devised to expedite the passage of food through the bowel. In short, all measures are designed to prevent a chemical autointoxication resulting from excessive and noxious bacterial activity. Yet Alvarez,[1] on the basis of a critical analysis of the literature on the origin of the symptoms in so-called autointoxication as well as his own experience as a gastro-enterologist, confidently concludes that the symptoms in intestinal stasis and constipation are due not to the absorption of any toxin but rather to a "mechanical distention and irritation of the lower bowel by the fecal masses." According to this investigator, the symptoms of so-called autointoxication result from the altered physiologic activity of other organs and tissues brought about by the stimulation of sensory nerves in a "distended, overactive, or wrongly acting bowel" in a sensitive, and often psychopathic, person. His position is at marked variance with the current chemical theory that an autotoxemia is the cause of the mental and physical manifestations of constipation. And since the treatment will depend on the cause, the medical profession will follow with more than academic interest the experimental development of a thesis so ably defended in this early presentation by one eminently fit to prosecute the work in the clinic as well as in the laboratory. Coincidently, more light will most certainly be thrown on the importance in the normal physiologic economy of man of that vast stream of sensory impulses continually pouring into the nervous system from the abdominal viscera through the interoceptors (Sherrington) so plentifully present along the entire gastro-intestinal tract. These visceral impulses rarely, under normal conditions, come into clear consciousness, and still elicit reflex acts which, in known instances, are of the greatest importance to man. An intensive study of this general visceral system will no doubt reveal facts of interest to the physiologist and of great practical importance to the clinician.

THE LOS ANGELES COUNTY HOSPITAL AND INTERNS

The Los Angeles County Hospital is one of the largest hospitals on the Pacific Coast, having 1,250 beds according to the latest report. Heretofore the requirements for the admission of interns have been sufficiently rigid that only graduates of better grade medical schools have been admitted to the staff. From a recent report, however, there appears to have been a serious change in this respect. Out of twenty-six interns at present in this hospital, eleven are reported as graduates of an osteopathic college, one is a graduate of dentistry, and one holds a diploma from the notorious Oriental University, a "correspondence" institution, at Washington, D. C. It is unbelievable that these interns could have secured their places had they been required to pass a thorough but fair examination, including practical and clinical tests, such as is used in testing the qualifications of interns by other high grade hospitals in the United States. Where high requirements are upheld, not only do the hospitals gain the best qualified interns, but the internships are more eagerly sought after. Any relaxation of requirements, however, by which poorly educated or incompetent graduates could secure internships, would produce the opposite effect. Graduates of high grade medical schools will avoid rather than seek internships in hospitals with easy or no educational requirements. They know that, as a rule, such hospitals are not conducted on a plane that will further their medical training. More particularly, however, they do not wish to be held partly responsible for bad conditions, if not scandals, which are liable to result from incompetence on the part of other members of the intern staff. It is hoped that the conditions at present in the Los Angeles County Hospital are only temporary, due perhaps to a war emergency, and that this otherwise splendid hospital will restore such strict regulations for admission to its intern staff as will not only uphold its reputation and guarantee a continued supply of competent interns but will also provide the best possible care for its patients.

THE 1919 ANNUAL SESSION A VICTORY MEETING

The principal feature at the annual session of the American Medical Association at Atlantic City next June will be the bringing together of medical delegates of the allied governments associated in the world war. It will be a victory meeting in which our confrères from other countries will help to celebrate the victory in which all had a part. It is contemplated that there will be conferences between representatives of the medical departments of the United States government and the foreign delegates relative to the good that may result from the experience of the various countries in medicine and surgery, especially in their military aspects. Undoubtedly deliberations will be held with a view to establishing and maintaining cooperative interallied graduate study and research—a most important subject at the present time. The main thing, however, will be to cement the bonds of an enduring friendship between members of the medical profession of the allied countries. This meeting has the approval of the Secretary of War: it will be semigovernmental in character. Invitations are being sent to the embassies and legations at Washington representing the allied governments. The Board of Trustees appointed a committee to have general charge of this feature. The constituent and component branches of the American Medical Association and the various medical centers undoubtedly will be called on in due time to do their part in extending the courtesies of the profession of the United States to these foreign delegates, as it is proposed that while here they will be given an opportunity of seeing our country.

Habits and Health.—Organized society may purchase the extinction of the malarial mosquito. It may buy the eradication of the yellow fever mosquito, the rat of bubonic plague, the tick of spotted fever, the fly of sleeping sickness, or the louse of typhus fever or of trench fever. Organized society may buy clean, pure water, and it may purchase a successful food inspection. But it cannot buy habits of personal hygiene that produce human health; that defend the individual from disease and postpone his death. It cannot purchase health habits that give the individual resistance to disease, making it harder for him to become sick and easier to recover. It cannot purchase the personal consciousness of individual obligation in the health affairs of the community that is essential to an effective defense of the community health.—T. A. Storey, M.D., Ph.D., on Physical Training.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending December 27, there were in the Medical Corps, 29,098 officers, a decrease of 949 since the previous week. This personnel includes four major-generals, five brigadier-generals, 221 colonels, 521 lieutenant-colonels, 2,462 majors, 9,452 captains and 16,433 lieutenants. There were in active service 28,357, a decrease of 875 since the previous week. Discharges to date include 6,231 officers.

New Medical Officers for Navy

As the result of examinations, held October 30 and 31, at various places throughout the country, of applicants for admission to the Medical Corps of the Navy, 144 officers of the U. S. N. R. F., and those holding temporary commissions were found qualified for appointment in a permanent establishment.

Death and Sick Rates in Army Camps

At present about 200,000 men are being discharged each week from the military service. All these men are given a thorough examination and are not discharged unless they are in as good a physical condition as Army medical treatment can make them. With this rapid diminution in the total number of men, the sick and death rates will inevitably rise, even though the number of sick men is diminishing, because the healthy men are being discharged. On the other hand, improvement in health conditions in all the camps may be expected because sanitary problems will become more simple with the decrease of the number of men in the camps.

Expedition to Turkey for Reconstruction Work

The Committee for Armenian and Syrian Relief it is reported is sending an expedition to Turkey for reconstruction work. Many hospitals are to be rehabilitated and a staff of twenty-five physicians is required. Only native born American citizens are eligible. The expedition will sail about the middle of January. Physicians with hospital experience in medicine and surgery and interested in war reconstruction work should communicate with Dr. George E. Washburn, 238 Commonwealth Avenue, Boston.

Prisoners Released

Hon. Dr. Henri S. Beland, C. A. M. C., St. Joseph de Beauce, Que., a member of the Canadian Parliament, who was in Belgium at the time the war broke out and was a prisoner for three years and was liberated by exchange, spoke regarding his experiences before the Boston Chamber of Commerce, December 12.——Lieut. Bernard J. Gallagher, M. C., U. S. Army, Minneapolis, who has been a prisoner in Camp Villingen, Germany, since March 28, has been liberated and is now in France.

Wounded

Capt. George C. Skinner, M. C., U. S. Army, Cedar Rapids, Iowa, is reported to be under treatment at a hospital in Paris, from wounds received, when a first aid station was bombed by German airplanes.——Capt. Henry B. Beeson, M. C., U. S. Army, Cornell, Wis., is reported to have been seriously wounded.——Lieut. John D. Colson, M. C., U. S. Army, St. Stephen, S. C., is reported to have been seriously wounded.——Lieut. James R. Martin, M. C., U. S. Army, Philadelphia, is reported to have been wounded severely.——Capt. Clifford H. Arnold, M. C., U. S. Army, Ardmore, Pa., is reported to have been wounded severely.——Lieuts. Isaac I. Parsons, M. C., U. S. Army, Media, Pa., and Cornelius T. McCarthy, M. C., U. S. Army, Philadelphia; Capt. Axel W. Swenson, M. C., U. S. Army, Bisbee, N. D., and Lieut. Ralph Emerson Buckley, M. C., U. S. Army, Hazleton, Pa., are reported to have been wounded in action, degree undetermined.

Mentally Defective in the Army

In a statement made to the senate committee on military affairs, December 13, Surgeon-General Ireland of the Army said that the number of mental and nervous cases requiring special treatment among soldiers in camps in this country is 2.5 per thousand. This is slightly above the number of cases in civil life. Among the troops overseas the number is 10 per thousand. Six hospitals abroad are used exclusively for treating these men, each base hospital having facilities for emergency treatment of the mentally defective. An interesting effect on shell-shock patients of the announcement of the armistice was that among 2,500 of these patients 2,100 were restored to normal within a day or two. It was brought out in the hearing that many men among the shell-shock cases had been decorated for extraordinary bravery in battle. The success of the Army medical examiners in keeping mentally defective men out of the service is shown by the fact that among the first 800,000 men examined, only 400 cases developed.

Reserve Officers' Training in Colleges

A large proportion of the 500 educational institutions in the United States which during the past year have devoted part of their efforts to military training of the students will now, under a new arrangement of the War Department, turn their attention to the Reserve Officers' Training Corps. Before the war there were about 115 units of the Reserve Officers' Training Corps in the various colleges. Under the demobilization order these were all abolished, but under the new arrangement about 100 of these are now being reestablished, and 200 applications for new units have been received. An important change under the new order is that the units will be allowed to specialize in training officers for the various corps of the Army, such as Medical Corps, field artillery, etc. Plans are also under way to establish junior units in the secondary schools. City high school corps are already established in Boston, Chicago, Denver and a number of other cities. A large part of the equipment used in the various institutions for the Students' Army Training Corps will be made use of for the Reserve Officers' Training Corps. The administration has been placed in the hands of the Committee on Education and Special Training of the War Plans Division of the general staff.

Proposed Changes in Army Medical Corps

Representative Dyer has recently proposed to amend the national defense act, as follows:

Section 1. That the medical department of the Army shall consist of one surgeon general with the rank of major general, who shall be chief of said department; assistant surgeon generals in the ratio of one-half of one per centum of the total number of officers of the medical department provided by law, the assistant surgeon generals to be equally distributed in the grades of major general and brigadier general of the medical corps, the dental corps, and the veterinary corps authorized by law, the commissioned officers of which shall be citizens of the United States, the enlisted force of the medical department of the Army as now provided by law.

Sec. 2. That commissioned officers of the medical corps below the rank of brigadier general shall be proportionately distributed in the several grades as now provided by law for the medical corps of the Navy.

Sec. 3. That hereafter the President shall be authorized to fill any vacancy that may occur in the commissioned personnel of the permanent establishment of the medical department of the Army of the United States by selection from the medical officers of the United States Army of not less than one year's continuous active service: Provided, That the selection shall be upon the efficiency rating and satisfactory examination of the officer, and where two or more officers are of equal rating selection will favor the one of longest service in the United States Army, Volunteer Army, National Guard, officers' reserve corps, or National Army: Provided further, That the officers so selected will be commissioned without loss of rank in the permanent establishment of the medical department of the Army of the United States, and such officers so commissioned shall be entitled to all pay, promotion, and allowances of officers of like rank in the permanent establishment of the Army of the United States, excepting that the rate of retirement pay shall be one-thirtieth of the present retirement pay, as now prescribed by law, for each year's service as enlisted man; or commissioned officer, or the total of such services in the United States Army, Volunteer Army, National Guard, officers' reserve corps, National Army, dental corps, dental reserve, or enlisted personnel in the Army or National Guard in any of the various departments of the Army of the United States: And provided further, That at the age now prescribed by law for retirement an officer to receive retirement pay shall have not less than 15 years' service in any or all branches enumerated in this act: And provided further, That the provisions of this act shall in like manner govern the filling hereafter of all vacancies in the dental corps of the United States Army: And provided further, That the ratio of dental surgeons now and hereafter commissioned shall be two dental surgeons per thousand of enlisted strength of the Army of the United States: And provided further, That all laws or parts of laws, in so far as they are inconsistent with the provisions of this act, are hereby repealed.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Alabama

To Army Medical School, from Camp Crane, Capt. M. E. SHERER, Childersburg.

To Camp Joseph E. Johnston, Fla., base hospital, from Fort Oglethorpe, Capt. C. C. WILEY, Birmingham.

To Camp Sheridan, Ala., from Fort Oglethorpe, Lieut. J. U. REAVES, Mobile.

To Fort McHenry, Md., from Fort Oglethorpe, Major C. T. POLLARD, Montgomery.

To Lakewood, N. J., from Fort Oglethorpe, Lieut. J. A. USSERY, Courtland.

To Long Beach, N. Y., from Camp McClellan, Lieut. G. LOTTERHOS, Birmingham; from Fort Oglethorpe, Lieut. L. C. ELLIS, Florence.

To Walter Reed General Hospital, D. C., from Camp Lee, Lieut. W. J. ROBBINS, Ensley.

Arkansas

To Camp Pike, Ark., from Fort Oglethorpe, Lieut. E. M. THOMPSON, Fort Smith.

To Camp Sherman, Ohio, base hospital, from Fort Oglethorpe, Lieut. A. H. COOK, Hot Springs.

To Chicago, Ill., from Fort Riley, Lieut. C. WALLIS, Arkadelphia.

To Mineola, N. Y., Hazelhurst Field, from Hoboken, Lieut. T. E. RHINE, Thorton.

To Whipple Barracks, Ariz., from New Haven, Capt. I. H. JEWELL, Paris.

California

To Army Medical School for instruction, from Fort Oglethorpe, Lieut. G. R. LATON, Los Angeles.

To Camp Fremont, Calif., base hospital, from Camp Dix, Major C. G. TOLAND, Los Angeles.

To Camp Kearney, Calif., from Fort Oglethorpe, Lieut. H. A. TODD, Visalia.

To Charleston, S. C., from the Surgeon-General's Office, Major L. F. LUCKIE, Los Angeles.

To Fort Des Moines, Iowa, from Camp Wadsworth, Capt. C. A. WARNER, Ontario; from Camp Wheeler, Lieut. C. S. YOUNG, Los Angeles.

To Fort MacArthur, Calif., from Fort Oglethorpe, Lieut. F. C. SWEARINGEN, Pomona.

To Newport News, Va., from Camp Lee, Major C. E. MORDOFF, San Francisco; Capt. A. F. BRADSHAW, Orange; Lieuts. A. A. McCLURKIN, Los Angeles; A. E. McDOWELL, Palo Alto.

To San Francisco, Calif., Presidio, from New Haven, Major F. P. GAY, Berkeley. As orthopedic surgeon, from Camp Fremont, Lieut. J. M. SMITHWICK, Byron Hot Springs.

To Washington, D. C., St. Elizabeth's Hospital, from Camp Crane, Capt. C. A. BELL, Santa Barbara.

The following order has been revoked: *To Camp Kearney, Calif.*, from Fort Oglethorpe, Capt. B. G. PINKERTON, Los Angeles.

Canal Zone

The following order has been revoked: *To Fort McPherson, Ga.*, Lieut. L. WENDER, Corozal.

Colorado

To Camp Alfred Vail, N. J., from Camp Crane, Lieut. W. H. STRATHMANN, West Toledo.

To Camp Gordon, Ga., base hospital, from Camp Sherman, Lieut. G. L. SHARP, Colorado Springs.

To Denver, Colo., from Camp Raritan, Capt. W. T. LITTLE, Canon City.

To Fort Logan, Colo., from Camp MacArthur, Major R. L. DRINKWATER, Denver.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to his proper station*, from Boston, Capt. C. G. McEACHERN, Denver.

To West Baden, Ind., from Camp Sevier, Capt. C. S. MORRISON, Colorado Springs.

Connecticut

To Army Medical School, from Fort Oglethorpe, Capt. T. F. BEVANS, Waterbury; from Walter Reed General Hospital, Major H. F. STOLL, Hartford.

To Camp Zachary Taylor, Ky., base hospital, from Camp McClellan, Capt. J. C. ROWLEY, Hartford.

To Fort McHenry, Md., from Fort Oglethorpe, Lieut. C. D. DEMING, Hartford.

To Fort Ontario, N. Y., from Camp Greene, Capt. F. E. WILSON, Hartford.

To Hoboken, N. J., from Camp A. A. Humphreys, Capt. W. R. MILLER, Southington; from Fort Oglethorpe, Capt. E. R. KELSEY, Winsted.

To Williamsbridge, N. Y., from Camp Lee, Capt. F. C. HYDE, Greenwich.

The following order has been revoked: *To Camp Upton, N. Y.*, from Fort Oglethorpe, Capt. J. D. GOLD, Bridgeport.

District of Columbia

To Camp Holabird, Md., as camp surgeon, from Walter Reed General Hospital, Lieut.-Col. J. E. Hall.

To Carlisle, Pa., from Washington, Col. F. R. KEEFER.

To Long Beach, N. Y., from Camp McClellan, Lieut. C. B. CONKLIN, Washington.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Rochester, Minn.*, Mayo Clinic for instruction, and on completion *to his proper station*, from Walter Reed General Hospital, Capt. L. [illegible]

To Washington, D. C[illegible] fice, from Eastern Department, Lieut. W. J. G. [illegible]

Florida

To Camp Forrest, Ga., from Fort Oglethorpe, Lieut R. O. COOLEY, West Palm Beach.

To Camp Joseph E. Johnston, Fla., base hospital, from Camp Wheeler, Lieut. W. H. WATSON, Lakeland.

Georgia

To Camp Custer, Mich., base hospital, from Fort Oglethorpe, Lieut C. B. BAILEY,. Hawkinsville.

To Camp Gordon, Ga., from Fort Oglethorpe, Lieut. H. B. BRADFORD, Atlanta.

To Camp Greene, N. C., base hospital, from Fort Oglethorpe, Lieut. B. DANIEL, Cordele.

To Camp Hancock, Ga., from Camp Wheeler, Major O. H. STANLEY.

To Camp Logan, Texas, base hospital, from Fort Oglethorpe, Lieut. R. F. WILSON, Atlanta.

To Camp Sherman, Ohio, base hospital, from Fort Oglethorpe, Lieut. M. S. RICHARDSON, Cedartown.

To Camp Wadsworth, S. C., base hospital, from Fort Oglethorpe, Lieut. J. R. McMICHAEL, Quitman.

To Corpus Christi, Texas, from Fort Oglethorpe, Lieut. T. STARR, Calhoun.

To Fort Benjamin Harrison, Ind., from Camp Sevier, Lieut. A. G. De LOACH, Atlanta.

To Fort Bliss, Texas, base hospital, from Fort Oglethorpe, Capt. R. T. AYCOCK, Monroe.

To Fort McPherson, Ga., from Camp McClellan, Major J. F. DENTON, Atlanta; from Walter Reed General Hospital, Capt. O. L. MILLER, Atlanta.

To Hoboken, N. J., from Camp Meade, Lieut. R. L. RHODES, Augusta.

To Newport News, Va., from Fort Oglethorpe, Lieut.-Col. W. H. RICHARDSON.

To Otisville, N. Y., from Fort Oglethorpe, Lieut. J. A. PRICE, Milledgeville.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to his proper station*, from Camp Gordon, Major F. H. PETTERS.

The following order hsa been revoked: *To Chicago, Ill.*, from Fort Oglethorpe, Capt. I. H. ADAMS, Macon.

Illinois

To Americus, Ga., Souther Field, as flight surgeon, from West Point, Miss., Capt. D. R. SCOTT, Macomb.

To Army Medical School, from Camp Pike, Lieut. J. C. SMALL, Chicago; from Fort Oglethorpe, Lieut. W. A. GROSS, Chicago.

To Camp Devens, Mass., from Lakewood, Lieut. C. M. BACON, Chicago.

To Camp Grant, Ill., as tuberculosis examiner, from Camp Crane, Lieut. J. SCHLESINGER, Oak Forest.

To Camp Greene, N. C., from Fort Oglethorpe, Lieut. R. W. E. SPRENG, Chicago.

To Camp Hancock, Ga., from Camp Lee, Capt. E. A. OLIVER, Chicago.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

KENTUCKY

New Officers.—At the annual meeting of the Jefferson County Medical Society, December 16, the following officers were elected: president, Dr. Claude G. Hoffman; vice presidents, Drs. Alphons R. Bizot and W. Barnett Owen; secretary, Dr. David Y. Keith, and treasurer, Dr. Henry B. Scott, all of Louisville.

MARYLAND

Johns Hopkins Unit Given Sailing Orders.—According to a cablegram dated from Paris, the Johns Hopkins Hospital Unit has received its sailing orders. This unit went abroad a year and a half ago. It was one of the first hospital units to go to France after this country entered the war. It is expected that the unit will be home about the middle of January.

Influenza May Cause Hospital at Frederick to be Closed.—Thirteen nurses at the City Hospital, including the superintendent, are ill with influenza and so crippled is the nursing force that it may be necessary to close the hospital unless help can be secured from other cities. All possible efforts are being made to secure help from other places. To relieve the situation as much as possible, twenty patients considered well enough to leave the hospital were sent to their homes, leaving twenty-two surgical and medical cases that must be given attention. No influenza patients have been received at the hospital, but in some manner the disease developed among the nurses. These cases are completely isolated. While conditions have improved, the epidemic has not abated in this city and in Frederick County.

State Association Assists Medical Officers.—Because many physicians on entering military service failed to send a list of their patients to the secretary of the state association, it is impossible for the state society to notify the patients of these physicians of their return to civil practice. To meet this situation the Medical Chirurgical Faculty of Maryland is supplying, in response to his application, a sufficient number of cards to each of its members as he again takes up civil practice to permit him to notify his patients and consultants in the name of the state organization that he has resumed practice. The card reads: "The Medical and Chirurgical Faculty of the State of Maryland announces that Dr....................... of .... has resumed the practice of medicine, having been honorably discharged from the Military Service of the United States."

MASSACHUSETTS

Somerville Physicians Change Hours.—The Somerville Medical Society has issued a notice systematizing the practice of medicine so the physicians may be able to see more patients. They have dropped the morning office hours and have adopted uniform hours from 2 to 7 p. m., excepting Sundays and holidays. Office hours are reserved for office patients, the other hours being occupied in house visits.

MICHIGAN

Smallpox.—Five new cases of smallpox were reported, December 10, in the epidemic at Adrian, and general vaccination was in progress. Influenza and other infectious diseases were less numerous, and it was expected that the schools would be reopened shortly.

MISSISSIPPI

Hospital Chartered.—A charter has been provided by the governor for the Ivy Hospital, West Point. It will have a capitalization of $7,000 and will be incorporated by E. P. and M. D. Ivy.

Personal.—Dr. Robert S. Curry, director of the bureau of venereal diseases of the state board of health, Jackson, has resigned on account of ill health.——Dr. M. L. Batson, Leakesville, has been appointed superintendent of the State Institution for the Blind, Jackson.——Dr. Roland Houston Cranford, Moselle, has been appointed superintendent of the Southern Mississippi Charity Hospital, Laurel.

Health Officers Hold Meeting.—At the annual meeting of the Mississippi Health Association held in Jackson, the first week in December, the following officers were elected: president, Dr. H. F. Harrison, Florence; vice presidents, Drs. Daniel J. Williams, Gulfport, Henry Boswell, superintendent of the State Tuberculosis Sanatorium, Magee, and W. D. Beacham, Summit, and secretary, Dr. Waller S. Leathers, University, executive secretary of the state board of health. Among the principal subjects for discussion were, the smallpox problem, the control of malaria, and rural sanitation.

MISSOURI

Hospital for Negroes.—The municipal authorities of St. Louis have purchased the buildings formerly occupied by the National University of Arts and Sciences and have altered and equipped them to serve as a city hospital for negroes. The staff of the hospital will be composed of negro physicians. Dr. Roscoe C. Haskell has been appointed superintendent of the institution.

Released from German Prisons.—The following Missouri physicians, who were held prisoners by Germany, have been released and probably now are in France or on their way home: Capt. Arthur H. Sewing, St. Louis; Capt. John F. Hardesty, Winfield, formerly of St. Louis; Lieut. Henry L. Rothman, St. Louis; Lieut. Louis M. Edens, Cabool, and Lieut. Harold A. Goodrich, Webster Groves.

Personal.—Dr. Abra C. Pettijohn, Brookfield, formerly superintendent of State Hospital No. 2 and later superintendent of the Eastern Oklahoma Hospital for the insane at Vinita, is now resident physician at the Dr. Charles R. Woodson Sanitarium, St. Joseph.——Dr. Adrien S. Bleyer, St. Louis, has arrived in France and has been assigned to the Children's Bureau of the American Red Cross.

Open-Air School for Subnormal.—An open-air school, combining the features of a boarding school and day school for girls of subnormal physique and deficient mental development, has been established by the St. Louis Tuberculosis Society, and the public school authorities at St. Louis. It is said to be the first institution of its kind, and the experiment will be tested for six months. The school opens with fifteen children in attendance.

MONTANA

Anaconda Isolation Hospital.—At a meeting of the city board of health of Anaconda, December 5, it was ordered that the capacity of the City Isolation Hospital be doubled. This will give accommodation for twenty-four patients.

Personal.—Dr. Max W. Barbour, Helena, has been reappointed physician of Lewis and Clarke Counties.——Dr. A. D. McDonald, superintendent of the State Tuberculosis Hospital, Galen, and for many years a representative in the state legislature, is reported to be seriously ill and has gone to Portland, Ore., for an operation.——Dr. Archie E. Williams, Havre, has been reelected physician of Hill County.——Dr. Daniel J. Donohue, Butte, president of the state board of health and major, M. C., Montana, N. G., was seriously injured, December 9, in a collision between his automobile and a street car.

NEW YORK

Personal.—Frank Richardson of Cambridge has been appointed commissioner of narcotic drug control by Governor Whitman.

Narcotic Drug Control Department Organizes.—November 1, the work of the Bureau of Habit Forming Drugs was transferred to the Narcotic Drug Control Department which was created by an act of the legislature of 1918. The new department will operate under the provisions of the habit-forming drug law of 1917 until Feb. 1, 1919, when that portion of the 1918 law relating to the sale, use, etc., of narcotic drugs becomes effective.

Penalty for Violation of Orders of Health Officers.—At Niagara Falls the city council passed an ordinance, effective December 10, making any violation of an order of the city health officer, Dr. Walter A. Scott, punishable by a sentence of six months in jail or a fine of $50 or both. Under the public health law the health authorities are obliged to bring an action in a civil court for a $100 penalty for violation of quarantine. The health officer showed that there had been 293 deaths from influenza since the beginning of the epidemic, and that there had been 6,049 cases of the disease. Of the deaths, 112 occurred since November 4, when the first general quarantine was lifted. The ban was restored after it had been off for two weeks.

New York City

Pasteur Institute Closed.—The Pasteur Institute of New York has closed its doors permanently, after nearly thirty years of service. Dr. George Gibier Rambaud, the last physician at the head of the institute, has received a commission in the National Army and has been ordered to service in France. In his valedictory for the institute he gave as the reason for discontinuing the work that the institute had fulfilled its purpose by introducing the Pasteur treatment into this country so that it was now given by all well appointed hospitals. Since 1910, the institute has treated more than 10,000 patients, four fifths of them without charge.

Health Board Stations to Sell Emulsified Milk.—Owing to the fact that the high price of milk has inflicted injury to the health of the city, and especially of the younger generation, the department of health announces that there will be placed on sale at the board of health stations an emulsified milk manufactured by the department of markets. This milk has been highly recommended by pediatricians, who say that it is equal to "Grade A" milk. The emulsified milk is made of ordinary milk with the butter fats extracted and the water dried off. This powder is the basis of the emulsified milk. It is to be retailed so as to supply emulsified milk at 11 cents a quart.

Slight Increase in Influenza.—For the week ending December 21 there were 1,707 deaths from all causes in this city, a rate of 15.17 per thousand population against 1,612, a rate of 14.66, for the corresponding week of 1917. This increase is due to influenza and pneumonia. The mortality from other disease is below normal; this is particularly true of such communicable diseases as measles, scarlet fever, diphtheria and whooping cough. The death rate of infants for the above named week was 76 per thousand births as against 89 for the corresponding week of 1917. Deaths due to organic disease were also below normal, while for tuberculosis they were approximately the same as for 1917.

Many Wounded Soldiers and Sailors Here.—There were in the hospitals of New York City and the vicinity, December 24, 42,077 sick or wounded soldiers, sailors, marines and nurses. The hospitals include the Debarkation, located in the old Greenhut Store building, Ellis Island, Hoffman Island, Grand Central Palace, Polyclinic, Fox Hills and the Gun Hill Road Hospital. The Red Cross provided a Christmas tree for every ward in these hospitals. Canes were distributed to every enlisted man, inscribed "Red Cross, 1919." Some 3,000 sailors and marines received fountain pens and nothing was left undone to make Christmas merry for every man in these hospitals.

Personal.—Dr. Anthony Bassler has been appointed professor of gastroenterology at Fordham University Medical School.——Dr. William V. P. Garretson has recently been appointed consulting neurologist to the Hospital of Functional Reeducation of Disabled Soldiers and Sailors, which is affiliated with Cornell University Medical College.——Dr. Ralph Herz, who until recently has been resident physician and pathologist of the Metropolitan Hospital, Blackwell's Island, has gone to Rochester, Minn., to become a member of the staff of the Mayo Clinic.——Dr. Nathaniel Blitzer, chairman of Local Draft Board 98, who was indicted on the charge of irregularities in connection with the enforcement of the selective draft law, has been exonerated, there being no evidence to sustain the charge.

Court Finds Difficulty in Defining "Diagnosis."—In the case of August Ziegler, a druggist, brought before the Long Island City Police Court, December 28, for practicing medicine without a license, the magistrate reserved decision for several days in order to consider the definition of "diagnosis." The testimony brought out showed that a woman had gone to the drug store complaining of a pain under her shoulder blade. Ziegler told her to go home, apply a mustard plaster, and go to bed, and to paint the sore spot with iodin. Being no better she returned two days later when he told her she had pleurisy and gave her a mixture to take. The accused admits this much but denies that he made a diagnosis of the ailment. Dr. Briggs, president of the Queens County Medical Society, called in to define "diagnosis," said that a physical examination was necessary while another physician call to testify stated that a physical examination was not necessary in order to constitute a diagnosis.

OHIO

Social Disease Bureau Established.—To cooperate with the U. S. P. H. S., the state department of health and the Cincinnati Health Department has established a bureau of social diseases, with offices in the Blymyer Building under the charge of Dr. Clarence J. Broeman. Clinics will be conducted on Tuesdays, Thursdays and Saturdays from 7 to 8 p. m.

Call District Physicians.—In Cincinnati, December 12, Dr. William H. Peters, Cincinnati health officer, had printed in the newspapers a list of district physicians in the city, advising citizens in need of medical services to employ them in instances in which they could not get the services of their regular physicians on account of the great number of influenza cases.

Personal.—Dr. Charles G. Augustus, U. S. P. H. S., recently appointed assistant director of public health of Springfield, has assumed the duty of his new position.——Dr. William H. White, Cleveland, formerly chief medical examiner of the state industrial commission, is said to have failed to secure reinstatement in that position, when the supreme court, December 10, granted the application of the commission preventing the Franklin County common pleas court from hearing Dr. White's appeal.

Qualify for State Hospital Positions.—The state civil service commission, Columbus, announced, December 12, the record of the examination held, December 10, for superintendent of the Cleveland State Hospital. In this competition Dr. Guy H. Williams, formerly assistant at Columbus State Hospital led, Dr. Harry H. McClellan, Dayton, formerly assistant superintendent at the Dayton State Hospital, was second, and Dr. Paul J. Alspaugh, assistant physician at the Massillon State Hospital, was third.

PENNSYLVANIA

Golden Jubilee.—The Medical Society of Franklin County will celebrate its golden anniversary on Jan. 21, 1919.

Physicians Found Guilty.—Dr. Ellsworth J. Trader, Pittsburgh, is said to have been convicted by a jury in the United States District Court, December 12, on an indictment containing twenty-one counts charging violation of the Harrison Narcotic Law. The Assistant United States Attorney announces that the defendant would soon be brought on other charges involving violation of the same law.

Supply of Nurses Deficient.—The state health department was hard pressed in the original outbreak of influenza and again in the present flareback affecting Altoona, Tyrone, Erie, Wilkes-Barre and other cities, for physicians and nurses. In many communities families insisted on the services of trained nurses. This drained the supply until the advice of the state health department was followed to pool interests by districting towns. This allowed a trained nurse and a physician for a given number of patients.

Personal.—Dr. William McKenzie, Conshohocken, presented a $100 liberty bond, with coupons attached, to the Montgomery County Medical Society, to be used as a nucleus of a permanent fund for a new home for the society.——Lieut. Ernest J. Hoover, M. C., who has been attached to the 369th infantry and stationed back of the front lines since May 12, is reported to be the first Altoona physician wounded, his leg having been broken when his air post was blown up by a shell.——Dr. Julius T. Vissel, Roaring Spring, suffered a cerebral hemorrhage, December 18, and is reported to be in very serious condition.——Dr. F. E. Downes, city superintendent of schools of Harrisburg, who had been critically ill, is reported to be convalescent.——Dr. Horatio C. Wood, Jr., professor of therapeutics at the University of Pennsylvania, is seriously ill in the University Hospital. It is feared he has contracted typhoid fever. During the influenza epidemic Dr. Wood devoted all his time to attending students of the Student Army Training Corps.——Dr. Frank C. Abbott of Jefferson Hospital unit has been decorated by the president of the French Republic with the "Medaille de la Reconnaissance Francaise." Dr. Abbott served in France more than three years before America entered the war.——Dr. John A. Presper has received word from his son, Capt. Elmer J. Presper, M. R. C., that he had been released from a German prison camp.——Major E. Hollingsworth Siter, M. R. C., now in France, will command an American Base Hospital to be established in Germany. For some time Major Siter has had charge of Base Hospital No. 68, A. E. F., at Mars-Sur-Allier.

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about $250, will be made on July 14, 1919, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be on any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the college on or before May 1, 1919. Each essay must be sent without signature, but must be plainly marked with the motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned on application within three months after the award. No Alvarenga Prize for 1918 was awarded.

Philadelphia

Influenza Still Prevails.—Influenza still prevails, but not to an alarming extent. There were thirty-seven new cases reported to the bureau of health, December 20.

Aid for Epidemic Patients.—For the purpose of research as well as aid to convalescent influenza patients, the Visiting Nurse Society has launched a complete follow-up investigation of the 4,050 cases of influenza under its care during the epidemic. The purpose is twofold: to help those who need money and to keep in touch with those who have apparently recovered without regaining normal vigor. The Emergency Aid and the National League for Women's Service are cooperating with the Visiting Nurses' Society in this follow-up work.

Personal.—Dr. Mervin Ross Taylor has been appointed medical officer of the Bell Telephone Company of Pennsylvania and associate companies.——Lieut. Orlando H. Petty, who served as surgeon with the Fifth Marines at Chateau Thierry, Belleau Wood and Soissons and who was gassed at Chateau Thierry, landed in New York, December 18.——Lieut. George G. Ross, Lieut.-Com. Robert G. Le Conte, Lieut.-Com. James E. Talley, Lieut. B. B. Vincent Lyon and Lieut. Jacob L. Herman have returned home from the war zone in France.——Dr. George Slonimsky has been appointed assistant medical inspector of the bureau of health.——Capt. Edwin S. Cooke, M. C., after fourteen months' service at a base hospital at Camp Meade, has returned to civil life and will resume his practice.——Dr. Edward Martin has accepted the position of health commissioner of Pennsylvania.

TENNESSEE

State Laboratory to Be Made Permanent.—At the meeting of the state board of health in Nashville, December 11, it was determined to continue as a permanent feature of health work in the state the laboratory recently established. A department of sanitary engineering was also one of the matters discussed. Vital statistics and the control of venereal diseases were other matters taken up. Influenza occupied the attention of the board during the meeting, Dr. Robert C. Derivaux of the United States Public Health Service giving a talk on the work of combating the epidemic in Nashville and Davidson County.

VIRGINIA

Society Meeting.—At the meeting of the Lynchburg and Campbell County Medical Society held at Lynchburg, December 2, Dr. John W. Dillard, was elected president, and Robert P. Kelly, both of Lynchburg, vice president, and Dr. Robert N. Younger, Snow Creek, secretary-treasurer.

Personal.—Dr. Robert C. Bryan has been appointed a member of the surgical staff of the Richmond City Home, to succeed Dr. H. Norton Mason, who has resigned.——Dr. Paul C. Spangler, Sutherland, charged with selling narcotics to soldiers, was exonorated at a hearing before a United States Commissioner, November 20.

CANADA

Hospital News.—The Calgary Hospital has had financial difficulties during the past year, and it is seeking an additional grant of $17,000 from the city to carry on the work for the balance of the year.

Personal.—Lieut.-Col. Charles A. Hodgetts, C. M. G., Ottawa, formerly medical adviser to the Canadian Conservation Commission, who has been overseas more than four years, has returned to Ottawa. Colonel Hodgetts was Canadian Red Cross Commissioner for three and a half years, and then entered the services of the British Ministry of Health, being stationed at various places in Ireland and England.——Capt. F. A. Atkinson, C. A. M. C., Alberta, has been awarded the Military Cross.——Dr. Ridley Mackenzie, McGill University, Montreal, is now on military duty at Bournemouth, England.——Dr. Arnold A. Halliday has returned from overseas and resumed practice in Toronto.

Personal.—The late Dr. A. Orr Hastings, brother of Dr. Charles J. C. O. Hastings, M. O. H., Toronto, left an estate of more than $100,000. More than $30,000 goes to hospitals and charitable purposes, the Hospital for Sick Children getting $4,000, and the Infants' Home, $2,000. The balance of the estate will go to relatives of the deceased.——Dr. Jacob Segal has been appointed medical superintendent of the Earl Grey Sanatorium, Regina, Sask., to replace Dr. Lester G. Houle, who has been transferred to the Tranquille Sanatorium at Kamloops, B. C.——Lieut.-Col. Percival K. Menzies, for the past year in charge of the surgical work at Orpington Hospital, England, has returned to Toronto.——Lieut.-Col. C. E. Cooper Cole has returned from overseas to Toronto.

Ontario Medical Act.—The Ontario government has given the medical profession another hearing before considering the new Ontario Medical Act. The examination question was under consideration. The University of Toronto favored one examination, and not any to be held by the Medical Council; but Dr. James C. Connell of Queen's University thought it not unreasonable that students should be required to pass the two examinations. Dr. Robert Ferguson, London, president of the Ontario Medical Council, speaking for the Western University of London, stated he was not aware that the Western University favored the abolition of the second examination. He also thought that the universities should each be considered a unit and have one representative on the Medical Council. At present the universities have six. He did not think it right that the University of Toronto should have three. Dr. Edmund E. King, Toronto, was opposed to Mr. Justice Hodgins' report that the representatives should be chosen by general election of the profession in the province. He said that the Medical Council and the profession generally favored the system of territorial election as at present—eight outside Toronto, and two within that city. The homeopaths had too many already. Dr. Alexander W. Crichton, Castleton, Ont., thought that the council should not have power to suspend the registration of a practitioner.

GENERAL

The Waste of Influenza.—As reported from Washington, December 10, out of 338,257 cases of influenza among the troops there were 17,000 deaths during the epidemic. In an address before the Association of Life Insurance Presidents in New York early in December, Henry Moir, president of the Actuarial Society of America, suggested that the total of about 400,000 deaths from the disease in this country meant an economic waste of ten million years.

Southern Surgeons Elect.—At the thirty-first annual meeting of the Southern Surgical Association held in Baltimore, December 18 to 20, the following officers were elected: president, Dr. J. E. Thompson, Galveston, Texas; vice presidents, Dr. Charles R. Robins, Richmond, Va., and George A. Hendon, Louisville, Ky.; secretary, Dr. Hubert A. Royster, Raleigh, N. C. (reelected), and treasurer, Dr. Guy L. Hunner, Baltimore (reelected). New Orleans was selected as the next place of meeting.

Comes to Aid Blind Soldiers.—Sir C. Arthur Pearson, head of the British National Institute, which is devoted to the care of men who have lost their sight in the war, and himself blind, sailed for the United States and Canada, December 20. The object of his visit is to confer with those responsible for the care of American soldiers blinded in the war and with Canadian authorities regarding the future welfare of Canadian soldiers trained at St. Dunstan's Hotel for Blinded Soldiers and Sailors, London.

Influenza.—The prevalence of influenza throughout the country is still great, with the general death rate increased over the normal by this disease and its complicating pneumonia. In no place, perhaps, is the disease occurring as frequently as at the height of the first wave in October and November. In most places there is a gradual subsidence as compared with the situation the first week or two following the peace celebrations, when there was an accession of cases. Indiana, for instance, reports a general and notable improvement, as do Wisconsin and Michigan. The army camps report a decided improvement. December 21, the Ohio State Medical Association through its executive secretary asked the Secretary of War to release at least two hundred Ohio physicians from the military service to aid in combating influenza in the rural districts of the state. Montana reports a regression in most communities, but in some there is still necessity for active measures. At Augusta, Me., December 17, restrictive measures, which had been suspended, were again to be enforced. In Alabama the disease was still the subject of concern by the state and local health authorities, especially at Montgomery. At Richmond, Va., it was reported, December 18, that of the 24,000 city schoolchildren one third were absent from the schools on account of the disease and the quarantine requirements in families having the disease. Illinois shows some improvements, but state officials warn that precautionary measures must not be relaxed. In Chicago and the north shore villages the situation was improving December 24. On that date there were 381 new cases of influenza and 126 new cases of pneumonia in Chicago, with eighty deaths from influenza and forty-three from pneumonia. There were twelve deaths in Evanston and the ban was not to be lifted on Christmas.

FOREIGN

Agitation in Spain for a Minister of Public Health.—The profession in Spain is making strenuous efforts for the centralization of the public health service as a government cabinet department. The *Medicina Ibera*, among other Spanish journals, is conducting an active propaganda, and is publishing a series of letters from leading physicians expressing their views on the subject. The letter from Ramon y Cajal is reproduced by photograph. He strongly endorses the idea and especially at the present moment, but he doubts whether the powers that be will consent to the creation of a new cabinet department, saying: "The higher spheres have little heed for hygiene, and to this appeal they will reply with arguments, not without some basis, as to the economical obstacles and the necessity for subordinating the hygienic measures, which often raise questions of a public order, to the ministerio de la Gobernacion, the only one, aside from the minister of war, which can impose effectual coercion." Parenthetically, Professor Cajal refers to his poor health, saying: "The cerebral arteriosclerosis from which I am suffering has become so much worse recently that I am obliged to refrain from writing, speaking and reading. Five minutes of any conversation induce intolerable congestion and headache, so I am compelled to a silence and solitude which are an actual martyrdom for me. I regret that I am unable to take up this matter of a ministry of public health as I should like to." He is now in his sixty-sixth year.

MEXICO LETTER

Mexico City, Dec. 12, 1918.

Epidemic of Influenza

The southeastern states of Mexico, Tabasco, Campeche and Chiapas, have now been invaded by the epidemic of influenza, and it is seizing numerous victims. When one reflects that the epidemic invaded Mexico from the north, at Laredo, and has followed a course from north to south, there is reason to fear that the disease will spread to Guatemala and invade Central America.

The Food Supply

Thanks to the good will of the government of the United States, the restrictions on the importation of foodstuffs into this country have been largely rescinded, and large quantities of wheat and flour have begun to arrive, which will reduce the price of bread to the benefit of all.

The University of Michoacán

On the first day of the new year there is to be inaugurated in the city of Morelia, state of Michoacán, the University of San Nicolas de Hidalgo. It will occupy the same buildings as the old Colegio de San Nicolas, founded during the Spanish rule, and of which Don Miguel Hidalgo, the father of his country, was the first alumnus and rector.

The new institution owes its inception to the governor, Ing. P. O. Rubio. It will comprise departments for law, medicine, pharmacy, engineering and belles-lettres. Dr. A. Oviedo is to be the rector, and various eminent physicians in the capital have been appointed honorary professors in the nascent university.

Child Welfare Congress

Official notice has been received of the postponement of the Congreso del Niño, which was to have been held this month in the city of Montevideo. Mexico had been invited to send delegates and had already appointed them.

Scarcity of Therapeutic Biologic Products

On account of the restrictions imposed on the exportation of therapeutic biologic products by the United States during the war just passed, there has been a notable scarcity of these curative agents. The production of therapeutic serums in the state Instituto Bacteriologico Nacional is not large, and in the private laboratories only bacterins are produced. There has been a special lack of antipneumococcus serum, and the little on hand has been held at exorbitant rates. It is hoped that in a short time this state of affairs will be remedied by the reestablishment of normal commercial relations.

Personal

Dr. F. Medina has been appointed secretary of the Mexican legation at Paris, and Dr. L. Rivero was given the position of third secretary. Both will soon leave for France, going by way of New York.

BUENOS AIRES LETTER

Buenos Aires, Nov. 11, 1918.

Epidemic of Influenza

From the middle to the end of October the epidemic spread until two thirds of the population had been attacked. Fortunately the mild cases predominated. The number of cases developing recently is smaller, but not the number of fatal cases. As a whole, however, the mortality has been much less than in the countries around us. In the last ten days of October there were 1,477 deaths, equal to the total death rate for the month of February. In the first five days of November, the average of deaths reached 162 daily, that is, twice the normal death rate of the city. Lesions in the lungs or bronchi or both were responsible for most of the fatal cases, but in some cases there were choleriform gastrointestinal symptoms suggesting cholera. Hemorrhages from the bowel, nose, etc., were not infrequent. Some of those affected presented eruptions resembling urticaria or measles, and exceptionally there was a hemorrhagic exanthem. Bacteriologic examination in the Hospital Muñiz revealed the Pfeiffer bacillus in the sputum of 60 per cent. of the patients, usually the graver cases. In a little more than 50 per cent., pneumococci or streptococci were found. In the fatal cases the Pfeiffer bacillus was found in 50 per cent., sometimes pure, but frequently associated with the pneumococcus or other germs.

The government, which neglected sanitary vigilance at the beginning, then took rigorous measures, closing the schools, cinemas, theaters and cafés. The public places were constantly disinfected, the streets profusely watered, etc.

The epidemic spread throughout the entire country, but nowhere has it yet acquired a gravity to compare with what has occurred in Rio de Janeiro and at Santiago in Chile.

Subscriptions for French Physicians

The national sympathy, which has always been on the side of the Allies, has just found expression anew in the subscriptions for the War Fund for French Physicians. The sum of 40,000 francs has been collected here for the fund.

Epidemics of Dysentery at Rioja and Catamarca

For the first time, dysentery has been officially recorded here and studied. There was an epidemic at Salta in 1917 and at Corrientes, but no bacteriologic work was done. The disease attacked children mostly, and the death rate was high. The predominant germs were the Flexner and atypical forms of dysentery bacilli. Diphtheria antitoxin gave appreciable results in treatment, but no decisive judgment is yet possible.

Dr. Escomel's Lecture

Dr.Edmundo Escomel of Arequipa, Peru, member of the Lima Academia de Medicina, recently delivered an address on intestinal trichomonosis at the Facultad de Medicina here.

Power of Students in Electing University Officers

The new government decree regulating the elections of officers for the universities provided that the dean, the Consejo Directivo and the Consejo Superior Universitario were to be elected by an assembly composed of the titular professors, an equal number of *profesores suplentes* and an equal number of students. The consequence was that the students made out lists and got every one of their candidates elected. In the Facultad de Medicina, Dr. Julio Mendez was elected dean; his nomination was resisted by the professors. When it came to a vote, he obtained the votes of fifty-eight students and of thirteen professors, while seventy-three of the professors cast their votes for Dr. Palma. The students then formulated diverse protests and declared a strike, insisting on the annulling of the electoral action. Dr. Palma then handed in his resignation, and a second assembly was held. On this occasion the students, without insisting on the annulling of the anterior election and without dwelling on the defects and irregularities on which they had previously laid great stress, succeeded in electing their candidate. It is very certain that the professors refrained from participating in this action.

This reform in the statutes of the university, as is readily seen, gives up the management of the university into the hands of the students.

PARIS LETTER

Paris, Nov. 28, 1918.

Removal of Sequestrums and Repair of Bone

This question was discussed at the recent Congrès français de chirurgie. Dr. de Fourmestraux of Chartres specified the indications for sequestrectomy and for immediate resection at the time of operating, that is, during the first day after the wounding. He claims that abstention is indicated in cases of fracture caused by a bullet coming with full force from an average distance, the fracture not spreading, and containing germs but with little evidence of infection. Recovery is rapid in these cases, which, however, are rather infrequently met. More often it is a question of a comminuted fracture, caused by a shell fragment or a bullet fired at a short distance with explosive effect, which scatters fragments of its jacket on its way. Instead of armed abstention, complete and thorough intervention is indicated. In cases of epiphyseal fracture, the projectile should be located roentgenographically and removed from the nearest surface point without heeding the portal of entry, then proceed to the closure of the articulation and early mobilization.

Dr. Viannay of Saint-Etienne has always obtained speedy results with Ollier's or Leriche's subperiosteal sequestrectomy or the intra-osseous operation of Tuffier. It is hardly possible to keep these patients in the advanced hospitals more than a few weeks, but they recover so quickly that when they leave the ambulance anatomic and functional restoration is complete in some by the eighth week.

Dr. Duvergey of Bordeaux, on the other hand, performs primary sequestrectomy very seldom, in fact, only when the sequestrum is completely denuded of periosteum. The operation required in recent complicated fractures: *débridement*, extraction of the foreign body, and clearing out of the wound, should respect the bone tissue. Carrel's method should be instituted as soon as possible because it overcomes infection effectively, and infection is a factor in the etiology of neuroses. Secondary sequestrectomy is done frequently, but it is indicated only when the presence of the sequestrum is confirmed by the roentgen ray and the probe. The clearing out then should be thorough so as to obviate repeated operations which fatigue and discourage the patient and often disseminate the infection and increase the trauma.

Dr. Salva Mercadé of Paris insists that not only must the adherent sequestrums be respected, but also the ends of the bone fragments themselves, with their stalactites and stalagmites which favor repair. Smoothing of the bone ends is one of the causes of pseudarthroses. Mercadé believes that primary sequestrectomy should be the rule; of thirty-eight patients operated on, only seven required a second operation. He reported sixty-four cases of compound fracture in which sequestrectomy was not done primarily, in which all came to late operation, necessitating much longer treatment. He claims that a compound fracture never escapes sequestrectomy; if not done early it must be done later, and it is in the interests of the patient to operate early.

So far as concern repair of losses of bone substance, surgeons resort to *plombage*, osteosynthesis or grafting as the case indicates. Dr. Duvergey condemns *plombage*, no matter what the substance employed to fill the cavity, because it is eliminated eventually. Dr. Olivier of Paris reported a case in which two *plombages* were done with six months' interval, and the local and general disturbances therefrom nearly necessitated the amputation of the member, and compelled two supplementary operations to remove the filling. Osteosynthesis is indicated in cases with great loss of bone substance and in which cicatrization appears to be impossible. Dr. Patel of Lyon reported fifty cases of osteosynthesis (thirteen of femur, twelve of tibia, twenty-four of humerus, and one of forearm) with only one failure (humerus). Union was effected in from two to six months.

As for bone grafting, surgeons are agreed that this operation should be deferred until several months after the closure of an infected wound. The graft can only be placed itno an aseptic bed. There must not be any scabs or skin eruptions, particularly not eczema, on or near the field of operation. The skin around might be curetted. Otherwise the graft is extruded, when everything must be done over again.

Summer Outings for Children

During the last summer of the war these summer outings for the schoolchildren became quite a feature. Many thousands of small Parisians were thus enabled to escape the menace of German bombs. In a report to the Paris city Council, M. Jean Varenne, commented favorably on the excellent results obtained in the eighteenth arrondissement of Paris by 1,400 children and seventy-six teachers from a stay of several months in the country. He asked that the Conseil municipal continue these outings during peace times because of the important bearing which they have on the future of the race (une oeuvre qui, pour l'avenir de la race, est du plus haut intérêt).

LONDON LETTER

London, Dec. 11, 1918.

The Health of Schoolchildren

The annual report of the chief medical officer of the board of education, Sir George Newman, has just been published. It contains results claimed to be "of exceptional value and extraordinary interest." A test inquiry into the physical condition of town and country children was made without previous warning. The number of children inspected was 1,362,063. In the London group, 7 per cent., and in the country group, 10 per cent. of the elder children were found to be absent from school on grounds of more or less chronic ill health, and after deduction of the blind, deaf, mentally and physically defective and invalid children of this age group drafted to special schools or absent from school, there were found to be suffering from one or more serious defects 24 per cent. of the children present at school. Of these children, 12 per cent. were ill nourished and 19 per cent. were unclean in body. Of the London children, 40 per cent., and of the country children, 65 per cent. had some carious teeth; 11 per cent. suffered from disease of the nose and throat; 10 per cent. had "very serious" defects of vision, while another 13 per cent. had defective eyesight of slightly less severity; 6 per cent. suffered from defective hearing and 6 per cent. from "severe" anemia; 4 per cent. had middle ear disease, 4 per cent. organic heart disease, 4 per cent. skin disease, and 4 per cent. spinal curvature of the "worst grade." These defective children were often two or more years behind their normal school standard, showing how physical weakness reacts on mental efficiency. Effective treatment of the kind now carried on by the board of education confers great benefit. Thus, London had sound teeth in 60 per cent., the country (where treatment is less thorough) in only 35 per cent. London had only 5 per cent. with disease of nose and throat, the country 21 per cent. London furnished only 2 per cent. of verminous heads, the country 8 per cent. Strenuous measures were taken in cleansing the children from vermin. One of the effects of the war has been the increase of uncleanliness and its associate conditions (verminous heads and bodies, ringworm, scabies, conjunctivitis, etc., owing partly to the lessening of parental supervision and partly to the introduction of infection from returning troops. Coming to the effects of the war on the children generally, Sir George Newman declares that the fear that the food rationing would bear hardly on the children has not been realized. In London it was found that the percentage of children in poorly nourished condition in the third term of 1917 was "considerably less than half the percentage found in 1913, the year before the war." Indeed, the figures for the third term of 1917 were the best in this respect ever obtained. The idea that "war bread" caused any bad symptoms was not confirmed on inquiry. Air raids, too, failed to affect the health of children, as it had been feared they might do.

Medical Representation in Parliament

The country is now in the throes of a general election in which the main appeal made by Mr. Lloyd George and his colleagues is that the men who brought the war to a successful conclusion should govern during the period of reconstruction. Medical questions scarcely enter into the election and certainly are not issues. In a previous letter, the formation of a medical parliamentary committee to insure a greater representation of the profession in Parliament was announced. For the nearly 700 seats of the House of Commons the number of medical candidates amounts to thirty-one. It does not appear that the medical parliamentary committee had anything to do with bringing forward any of these candidates, but it is offering to supply speakers to support medical candidates. The idea is that medical members of Parliament should do everything possible in promoting measures to improve the health of the people. Most of the medical candidates are appealing for support as members of the various political parties and, therefore, not as physicians; but in the case of the elections for the universities, for which there are six medical candidates, a special appeal is being made to the medical graduates, who form a large proportion of the electors. These candidates are all men of professional eminence. They are Sir William Whitla (Queen's University, Belfast); Sir Robert Woods (Dublin University); Sir Wilmot Herringham (London University); Sir Watson Cheyne, Dr. Peter MacDonald and Principal W. R. Smith (Scottish universities).

White Bread Again

With the cessation of hostilities, the use of a dark flour constituting a high percentage of the grain is no longer compulsory, and white bread again appears on our tables, to the great satisfaction of most persons. It is curious that although both before the war and during the war the advantages of whole-meal bread, or something approaching it, were pointed out, no impression has been made on the public. Even a press campaign by the most widely read newspaper produced little effect. In spite of dietetic teaching, people prefer what is more pleasing to the eye and gratifying to the palate, white bread.

The Influenza Epidemic

The influenza epidemic is declining in the United Kingdom, but new cases still occur, and pneumonia continues to take a serious toll of life. In India the epidemic has been severe. In Bombay city there were 15,000 deaths, and in Delhi city, of a population of 200,000, the death rate at one time reached 800 daily. In the rural tracts beyond the reach of effective prophylactic measures, the loss has been tremendous. In the Punjab the first signs appeared in August. In September it persisted in a mild form, and from the middle of October until November 8 it was acute. It is estimated that the number of deaths ranges from 5 to 10 per cent. of the population. The death roll is heaviest among young adults and women. The number of deaths in the Punjab is estimated at 250,000. When the final results of the epidemic are summed up, it will probably be found that other provinces have suffered on approximately the same scale. No part of the country seems to have escaped, although the visitation was lightest in Bengal, and even the dry and bracing Himalayan tracts are reported to have been severely attacked.

Venereal Disease and Demobilization

In the middle ages, outbreaks of syphilis followed in the wake of armies. The danger of diffusion of venereal diseases on the demobilization of the present huge armies is therefore to be borne in mind. It is estimated that 2 per cent. of the British army is affected by venereal disease, a proportion which is regarded as much lower than that of the adult civil population. The medical instruction of soldiers with a view to prevention, and the adoption of early treatment, explain the difference. However, the total number of infected soldiers and sailors is estimated at from 200,000 to 300,000, which constitutes a grave danger to the civilian population on demobilization, when the disciplinary influence of army life will cease. The National Council for Combating Venereal Diseases has published recommendations which will no doubt receive the careful consideration of the authorities. The most important is the suggestion that soldiers or sailors should not be discharged while in an infective state.

Marriages

Alfred E. Rhein, Rosedale, Ind., to Miss Susan Pillars Miller, Terre Haute, Ind., November 5.

Philip Embury, to Miss Marie Katherine Stein, both of Basking Ridge, N. J., December 18.

Edward James Lewis, to Miss K[redacted] Sproe[illegible] [illegible]th of Chicago, December 18.

Deaths

Rear Admiral Henry Gustav Beyer ⊕ Medical Director, U. S. Navy, retired; aged 68; died at his home in Washington, December 10. Dr. Beyer was born in Saxony, Germany, ctober 28, 1850, received his preliminary education and took course in pharmacy in Germany, and then entered Bellevue ospital Medical College, from which he was graduated in 1876. He received the M. R. C. S. degree in London, in 1881, and was given the degree of Ph.D. by Johns Hopkins University, in 1887. He entered the Navy, as assistant surgeon, immediately on graduation, was made passed assistant surgeon in 1880, surgeon in 1893, medical inspector in 1905, medical director in 1910, and rear admiral, Feb. 27, 1911, and was retired on attaining the age of 62 years, Oct. 28, 1912. During his thirty-six years of service in the Navy, he had twelve years and ten months of sea service, and three years on special duty at the Smithsonian Institution, Washington, and was on special duty in Washington, for two years. He was professor of hygiene in the Naval Medical School, Washington, from 1904 to 1912, and was also lecturer on Naval Hygiene in the War College, Newport, R. I. He was a member of the Association of Military Surgeons of the United States, National Society for the Study and Prevention of Tuberculosis, American Public Health Association, and American Association of Pathologists and Bacteriologists, and was a prolific contributor to medicomilitary literature.

Rear Admiral Henry G. Beyer, M. C., U. S. Navy, 1850-1918

Hudson J. Winnett, Lincoln, Neb.; Long Island College Hospital, 1870; aged 72; at one time a member of the Nebraska State Medical Association; formerly a member of the City Council and mayor of Lincoln, and state railway commissioner in 1906; trust officer of the Lincoln Trust Company; died in Johns Hopkins Hospital, December 19, after a surgical operation.

William T. Wright, Denison, Iowa; University of Michigan, Ann Arbor, 1882; aged 62; a member of the Iowa State Medical Association and formerly secretary of the Crawford County Medical Society and physician of Crawford County; formerly coroner of Monona County; died at the home of his brother-in-law in Ute, Iowa, November 30, from pneumonia following influenza.

Asa Charles McCurdy ⊕ Major, M. C., U. S. Army, Battle Creek, Mich.; University of Michigan, Ann Arbor, 1908; aged 32; who after training at Camp Crane, Allentown, Pa., went to Italy and was then transferred to France, and attached to the Fifty-Second Engineers; died in Brest, France, November 28, from the effects of a carbuncle on the face.

Charles Hedinger, Canton, Kan.; University of Goettengin, Hanover, Germany, 1842; aged 96; for two years and a half a surgeon in the United States Navy, and later in the Medical Corps, U. S. Army, and surgeon throughout the Civil War; coroner of Pottawatomie County, Kan., for eleven years; died at his home, December 12, from acute gastritis.

Arthur Holmes Brown ⊕ Auburn, N. Y.; Long Island College Hospital, Brooklyn, 1882; aged 64; formerly president of Cayuga County Medical Society, and Auburn Academy of Medicine; a director of the New York State Automobile Association; was instantly killed in an automobile accident, near Camillus, N. Y., December 19.

George K. Sims, Richmond, Va.; University of Virginia, Charlottesville, 1894; aged 53; a member of the Medical Society of Virginia; Acting Assistant Surgeon, United States Army, for four years during and after the Spanish-American War with service in the Philippine Islands and Hawaii; died at his home, recently.

Millville Charles Korb, Chicago; Bennett Medical College, Eclectic, Chicago, 1896; University of Illinois, Chicago, 1907; aged 50; a member of the Illinois State Medical Society; died in the Washington Boulevard Hospital, Chicago, December 21, from nephritis.

George Baney Wolff ⊕ Towson, Md.; Johns Hopkins University, Baltimore, 1912; aged 33; a member of the staff of the Sheppard and Enoch Pratt Hospital, Towson; was shot and instantly killed by Dr. Noburu Ishida, a Japanese member of the staff, December 21.

Paul Morgan Strother ⊕ Lynchburg, Va.; University of Virginia, Charlottesville, 1906; aged 34; a specialist in roentgenology; died November 26, as the result of injuries received in the overturning of his automobile the day before.

Samuel Cecil Bowen, Richmond, Va.; Medical College of Virginia, Richmond, 1905; aged 37; a member of the Medical Society of Virginia; associate professor of laryngology in his alma mater; died in Chicago, December 20, from pneumonia following influenza.

Reese Davis ⊕ Lieut., M. C., U. S. Army, Forest City, Pa.; Jefferson Medical College, 1916; aged 25; formerly intern in the State Hospital of the Northern Anthracite Region of Pennsylvania, Scranton; died in France, September 27, from wounds received in action.

William Chester Smith ⊕ Captain, M. C., U. S. Army, Chicago; University of Louisville, Ky.; 1904; University of Illinois, Chicago, 1913; aged 38; on duty at Camp Sherman, Chillicothe, Ohio; died at that post, December 11, from valvular disease of the heart.

William Pounder Gillespie, Jr. ⊕ Philadelphia; Jefferson Medical College, 1904; aged 37; assistant medical examiner for the Pennsylvania System, at the Broad Street Terminal; died in the Presbyterian Hospital, Philadelphia, October 9, from lobar pneumonia.

William F. Carroll, Macon, Ga.; Medical College of Georgia, Augusta, 1877; aged 68; at one time a member of the Medical Association of Georgia; city physician of East Macon for several years; died at his home, November 30.

Homer Joseph Slocum ⊕ Lieut., M. C., U. S. Army, Carrollton, Ky.; Louisville, Ky., Medical College, 1903; aged 39; on duty at Camp Greenleaf, Fort Oglethorpe, Ga., died at that post, October 17, from pneumonia following influenza.

Robert Newcomb McHenry, Millville, N. H.; University of Pennsylvania, Philadelphia, 1912; aged 29; a member of the Medical Society of New Jersey; coroner of Cumberland County; died in a hospital in Philadelphia, December 17.

Edward B. Greene, Chicago; Northwestern University Medical School, Chicago, 1885; aged 64; at one time a member of the Illinois State Medical Society; died in the North Chicago Hospital, Chicago, December 17, from diabetes.

Edward Sherman Breese ⊕ Dayton, Ohio; Medical College of Ohio, Cincinnati, 1899; aged 52; for several years resident surgeon at the National Military Home, Dayton; died at his home, December 15, from carcinoma of the stomach.

William George Turner ⊕ Captain, M. C., U. S. Army, Fall River, Mass.; Baltimore Medical College, 1904; aged 39; on duty at Fort Benjamin Harrison, Ind.; died at that post, October 11, from pneumonia following influenza.

Joseph Randall Polk, Nashville, Tenn.; Vanderbilt University, Nashville, 1918; aged 27; died at an infirmary in Nashville, December 1, from pneumonia following influenza.

James Richard Kirby, Clinton, Mass.; Baltimore Medical College, 1902; aged 42; a member of the Massachusetts Medical Society; died at his home, September 29, from bronchial pneumonia following influenza.

George M. Paullin, Bridgeton, N. J.; University of Pennsylvania, Philadelphia, 1861; aged 79; Acting Assistant Surgeon in the Army during the Civil War; died at his home, September 18, from heart disease.

Luther A. Rexford, Minneapolis, Minn.; Minneapolis College of Physicians and Surgeons, 1907; aged 36; at one time a member of the Minnesota State Medical Association; died at his home, about December 20.

Abram C. Miller, Turin, N. Y.; University of Vermont, Burlington, 1876; aged 70; health officer of the town and village of Turin and town of Grieg; died at his home, October 13, from pneumonia.

Francis Robert DiMatteo, Newark, N. J.; Baltimore, Md., Medical College, 1903; aged 37; a member of the Medical Society of New Jersey; died at his home, October 13, from pulmonary tuberculosis.

Edwin Franklin Syrop ⊕ Lieut., M. C., U. S. Army, Bayonne, N. J.; University of Maryland, Baltimore, 1916; aged 28; died in Base Hospital No. 78, France, October 27, from lobar pneumonia.

Thomas David Stephens, Penn Run, Pa.; University of Pittsburgh, 1895; aged 50; a member of the Medical Society of the State of Pennsylvania; died in the Indiana, Pa., Hospital, December 13.

William James Douglas, Newark, N. J.; University and Bellevue Hospital Medical College, New York City, 1908; aged 34; died at his home, October 16, from pneumonia following influenza.

Joseph M. Shorts, West Liberty, W. Va. (license, West Virginia, 1881); aged 66; died at the North Wheeling, W. Va., Hospital, December 18, from pneumonia following influenza.

Charles W. Ott ⊕ Higginsville, Mo.; Kansas City, Mo., Homeopathic Medical College, 1899; aged 40; died at his home, October 4, from lobar pneumonia, following influenza.

Russell Ernest Boyle, Alliance, Alberta; University of Manitoba, Winnipeg, 1916; aged 30; died at his home, November 10, from pneumonia following influenza.

Davis King Summers ⊕ Lieut., M. C., U. S. Army, Chattanooga, Tenn.; Emory University, Atlanta, Ga., 1915; aged 30; was killed in battle in France, March 1.

Louis Aimé Maynard, Worcester, Mass.; University of Vermont, Burlington, 1889; aged 58; died in his apartment, December 5, from pulmonary hemorrhage.

Otto Andrew Koch, Germantown, Philadelphia; University of Pennsylvania, Philadelphia, 1896; aged 47; died at his home, October 30, from tuberculosis.

Lynn Luzerne Lorenz ⊕ Rockford, Iowa; University of Illinois, Chicago, 1912; aged 29; died at the home of his parents in Rockford, December 1.

Adolphe Olivier, Montreal, Que.; Laval University, Montreal, 1918; aged 27; died in Montreal in October from pneumonia following influenza.

Aristide Dubuc, Montreal, Que.; Laval University, Montreal; aged 28; died in Montreal in October, from pneumonia following influenza.

Frank Justin Barker, Concord, Mass.; Dartmouth Medical School, Hanover, N. H., 1888; aged 56; died in Carthage, N. Y., December 14.

Romeo Picotte, Montreal, Que.; Laval University, Montreal, 1918; aged 26; died in Montreal, in October, from pneumonia following influenza.

Frank Marion Mullins, Fort Worth, Texas; Bellevue Hospital Medical School, 1883; aged 54; died at his home, December 11.

Emily James Davis, Marion, Ind.; Curtis Physio-Medical Institute, Marion, Ind., 1892; aged 48; died at her home, December 8.

Oswald W. Cosby ⊕ Monroe, La.; Marion-Sims College of Medicine, St. Louis, 1896; aged 43; died at his home, in October.

Charley I. Hammond, Baltimore; Maryland Medical College, Baltimore, 1905; aged 50; died at his home, November 21.

John Ivison, Coatesville, Pa.; University of Pennsylvania, Philadelphia, 1874; aged 71; died at his home, October 15.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MISBRANDED NOSTRUMS

How the Bureau of Chemistry Is Protecting the Public Against Fraudulent or Misleadingly Advertised "Patent Medicines"

Paine's Celery Compound.—Shipped by Wells & Richardson Co., Burlington, Vt. Analysis showed alcohol, 18.5 per cent., potassium nitrate, sugar and glycerin, with calisaya, celery, blackhaw and sarsaparilla indicated. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5021.*]

Botanic Blood Balm.—Shipped by Wm. R. Warner & Co., Philadelphia. Analysis showed alcohol, 14.6 per cent., potassium iodid, arsenic trioxid, and guaiac, with sarsaparilla and senna indicated. Falsely and fraudulently advertised. Fine, $200.—[*Notice of Judgment No. 5022.*]

Owens' Wonderful Sore Wash.—Shipped by Wedard W. Zurhellen, manager of the Sore Wash and Eye Lotion Co., Natchez, Miss. Analysis showed hydrastin, zinc salt, sulphate, chlorid and sodium present. Falsely and fraudulently advertised. Fine, $10 and costs.—[*Notice of Judgment No. 5023.*]

Lafayette Cough Syrup.—Shipped by Lafayette Co., Berlin, N. H. Analysis showed 75 per cent. sugars, 7.34 per cent. alcohol, ipecac alkaloids, wild cherry, and a trace of benzoic acid. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5024.*]

Gilbert's Gravel Root Compound.—Shipped by Thomas H. Gilbert Drug Co., Huntsville, Ala. Analysis showed over 14 per cent. alcohol with lithium, benzoic acid, and emodin, and indications of cascara, licorice and juniper. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5025.*]

Strange's Rheumatic Remedy.—Shipped by Howell M. Strange, Birmingham, Ala. Analysis showed the product to be, essentially, a mixture of baking soda and magnesium carbonate. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5028.*]

Baur's Diamond Brand Bromides.—Shipped by the Liquid Carbonic Co., Minneapolis. Analysis showed the preparation to be a granular effervescent salt, containing chiefly baking soda, citric acid, Epsom salt, a small amount of caffein and but a trace of bromid. Falsely and misleadingly advertised. Fine, $10.—[*Notice of Judgment No. 5035.*]

S. B. Cough & Consumption Remedy.—Shipped by the Blumauer-Frank Drug Co., Portland, Ore. Analysis showed alcohol, morphin sulphate, chloroform, tar and sugar. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5063.*]

Gowan's Preparation.—Shipped by the Gowan Medical Co., Chicago. Analysis showed that the product consisted, essentially, of a wool-fat vehicle containing about 12 per cent. camphor, 0.7 per cent. quinin sulphate and about 20 per cent. of water. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5084.*]

Urol.—Shipped by Joseph C. Ligeour and Chesleigh A. Holtzendorf, who traded as the Standard Chemical Co., Fitzgerald, Ga. Analysis showed that Urol was a solution of volatile oils in balsam. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5085.*]

Boxenbaum Discovery.—Shipped by Beni Boxenbaum, who traded as Boxenbaum, Son & Co., Philadelphia. Analysis showed the stuff to be, essentially, a watery solution of potassium bromid, with a small amount of a cathartic drug. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5089.*]

Tablets Creavita.—Shipped by Inter-American Pharmacal Corp., New York City. Analysis showed the tablets to contain, essentially, chromium sulphate, calcium carbonate, phenolphthalein, strychnin and starch. Falsely and fraudulently advertised. Company pleaded guilty; sentence suspended.—[*Notice of Judgment No. 5120.*]

Old Lady Fulten's Comforting Pills.—Shipped by Sharp & Dohme, New York City. Analyses showed the pills were composed, essentially, of reduced iron, strychnin, and a laxative drug. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5122.*]

C. C. C. (Crownall Elastic Capsules).—Shipped by Hance Bros. & White, Philadelphia. Analysis showed these to be gelatin capsules containing, essentially, oil of cubeb and balsam of copaiba. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5123.*]

Victor Injection, No. 19 Compound, No. 6 Compound.—Shipped by the Victor Medicine Co., St. Louis. Analyses showed "Victor Injection" to be an aqueous solution of ichthyol; "No. 19 Compound" and "No. 6 Compound" to be essentially milk sugar. All three products falsely and fraudulently advertised. Fine, $600.—[*Notice of Judgment No. 5124.*]

Hemogenas Pills.—Shipped by Sharp & Dohme, New York City. Analysis showed the pills to be compounded, essentially, of reduced iron, a small amount of unidentified alkaloid, a laxative drug, and phosphorus compounds. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5125.*]

Restorative Tablets—Fountain of Health.—Shipped by Sharp & Dohme, New York City. Analysis showed the tablets to contain, essentially, reduced iron, quinin, strychnin, and a laxative drug. Falsely and fradulently advertised. Fine, $10.—[*Notice of Judgment No. 5126.*]

Denn's Strong, Sure, Safe and Speedy Stomach, Liver, Kidney, and Rheumatism Remedy.—Shipped by Henry Denn, trading as Denn's Rheumatic Cure Co. Analysis showed alcohol, 8.2 per cent., over 50 per cent. of sugar, traces of glycerin, and indications of licorice and cascara sagrada. Falsely and fraudulently advertised. Fine, $50 and costs.—[*Notice of Judgment No. 5130.*]

Dr. Navaun's Mexican Lung Balm, and Kidney Tablets.—Shipped by Edward S. and Clifford S. Navaun, trading as the Botanic Drug Co., Detroit. Analyses showed the "Lung Balsam" to be, essentially, a syrup containing vegetable extractives and small quantities of chloroform and alcohol, and the "Kidney Tablets" to contain methylene blue, potassium nitrate, juniper, and calcium carbonate. Both were falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5131.*]

Dr. Chas. De Grath's Electric Oil.—Shipped by Margaret Hutton Kemp, Samuel H. Ordway and Edward C. Mears Kemp, executors of the estate of George William Kemp, trading as Lanman & Kemp, New York City. Analysis showed the product to consist, essentially, of fixed saponifiable oil, turpentine, oil of cinnamon, ammonium compounds and chloroform, with indications of the presence of a small amount of mineral oil. Falsely and fradulently advertised. Fine, $20.—[*Notice of Judgment No. 5136.*]

Bovinine.—Shipped by the Bovinine Co., New York City. Analysis showed the product to be a blood preparation containing 11 per cent. alcohol, and over 6 per cent. glycerin. Falsely and fraudulently advertised. Company pleaded guilty; sentence suspended.—[*Notice of Judgment No. 5170.*]

Fritch's Vegetable Liniment.—Shipped by John A. Fritch, St. Louis. Analysis showed it to be essentially an alcoholic solution of chloroform, turpentine, camphor, capsicum, oil of cloves, methyl salicylate, and free ammonia. Falsely and fraudulently advertised. Fine, $20 and costs.—[*Notice of Judgment No. 5171.*]

Perkins' National Herbs Blood Purifier Kidney and Liver Regulator.—Sold by National Herb Co., Washington, D. C. Analysis showed it to contain practically 40 per cent. sugar, 11 per cent. carbonate of lime, with a cathartic drug and strychnin present. Falsely and fraudulently advertised. Fine, $75.—[*Notice of Judgment No. 5175.*]

Dr. Lemke's Golden Electric Liniment, and St. Johannis Drops.—Shipped by C. H., E. S., C. R., and W. H. Lemke, A. Cromer, and C. Cross, who traded as Dr. H. C. Lemke Medicine Co., Chicago. Analysis showed the "Golden Electric Liniment" to contain over 62 per cent. alcohol, with chloroform, free ammonia, camphor, and red pepper present, and oil of sassafras and volatile oil of mustard probably present. Analysis showed the "St. Johannis Drops" to contain 43 per cent. alcohol, with morphin, camphor, a laxative drug, red pepper and aromatic oils present. Both products falsely and fraudulently advertised. Fine, $5 and costs.—[*Notice of Judgment No. 5176.*]

Mentholatum.—Shipped by Edward K. Hyde, trading as the Mentholatum Co., Buffalo. Analysis showed the product to be essentially petrolatum, with about 5 per cent. boric acid and 10 per cent. menthol and camphor. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5178.*]

Enteronol.—Shipped by the Enteronol Co., Oswego, N. Y. Analysis showed the preparation to consist essentially of alum, camphor, ginger, red pepper, tannic acid and phenolphthalein. Falsely and fraudulently advertised.[1] Fine, $200.—[*Notice of Judgment No. 5179.*]

Dr. Harter's Lung Balm.—Sold by the Dr. Harter Medicine Co., Philadelphia. Analysis showed the preparation to contain over 60 per cent. sugar, 3.65 per cent. alcohol, chloroform, cinnamic acid and plant extractive material, with indications of traces of antimony and tartrates. Falsely and fraudulently advertised. Fine, $200.—[*Notice of Judgment No. 5188.*]

Dr. O. Phelps Brown's Herbal Ointment.—Shipped by the Kells Co., New York City. Analysis showed the preparation to be essentially 98.5 per cent. petrolatum, and 1.5 per cent. salicylic acid. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5212.*]

Taylor's Horehound Balsam.—Shipped by W. Scott Taylor, trading as the Taylor Drug and Chemical Co., Trenton, N. J. Analysis showed the preparation to contain 14.5 per cent. alcohol, 46.7 per cent. sugar, with chloroform, methyl salicylate, horehound, camphor, and a trace of ipecac. Falsely and fraudulently advertised. Taylor pleaded guilty; sentence suspended.—[*Notice of Judgment No. 5214.*]

Breeden's Rheumatic Cure.—Shipped by Carroll C. Breeden, trading as the Breeden Medicine Co., Memphis, Tenn. Analysis showed the product to contain 12.6 per cent. alcohol, with potassium iodid, guaiac and probably extract of colchicum seed and colocynth. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5224.*]

Sulphur Bitters.—Shipped by Allen P. Ordway, trading as A. P. Ordway & Co., New York City. Analysis showed the product to have over 21 per cent. alcohol, with sulphur, aloes and another laxative drug present, and with indications of wild cherry. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5234.*]

Dr. DeWitt's Eclectic Cure; Dr. DeWitt's liver, Blood and Kidney Remedy.—Shipped by W. J. Parker, trading as W. J. Parker Co., Baltimore. Analysis showed the "Eclectic Cure" to consist essentially of alcohol, water, ether, oil of sassafras, red pepper, and opium alkaloids, with lobelia indicated. The "Liver, Blood and Kidney Remedy" was shown by analysis to consist essentially of an alcohol-water extract of buchu and rhubarb, with iodids, nitrates, chlorids, and sulphates of magnesium, calcium, sodium and potassium. Falsely and fraudulently advertised. Fine, $20 and costs.—[*Notice of Judgment No. 5240.*]

Payne's Sylax.—Shipped by Edward C. Seyler, trading as the German Medicine Co., Cincinnati. Analysis showed the preparation to consist essentially of a laxative drug, plant extractive matter, Epsom salt, sugar, alcohol and water, with a white powder at the bottom of the bottle, consisting principally of sulphate of lime. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5269.*]

---

[1] This nostrum was examined by the chemists of the A. M. A. Chemical Laboratory ten years ago, and the fraudulence of the product was declared in The Journal, March 21, 1908.

Dr. Bell's Pine Tar Honey.—Sold by E. E. Sutherland Medicine Co., Philadelphia. Analysis showed it to be an alcohol-water solution, containing ammonia, glycerin, pine tar, sassafras, red pepper, reducing sugars, a laxative drug and alkaloids. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5271.*]

Lung Germine.—Shipped by the Lung Germine Co., Jackson, Mich. Analysis showed the preparation to be a water-alcohol solution, containing free sulphuric acid and iron sulphate. Falsely and fraudulently advertised.[1] Fine, $50.—[*Notice of Judgment No. 5280.*]

Correspondence

EFFECT OF INFLUENZA ON THE HEART

To the Editor:—Many physicians, no doubt, have frequently seen cases of influenza in which, usually after the fever has subsided, the pulse is slow and easily compressed, and the patient complains of dizziness, extreme weakness and depression, and on attempting to get up often falls into a faint.

Examination usually reveals a slow heart with sounds somewhat muffled, giving the impression to the ear of a tired out heart. This condition is usually taken to be one of myocarditis, and frequently it has been stated that in the future we shall have a great many cases of myocarditis and other heart conditions to contend with.

In taking the blood pressure, invariably I have found the diastolic pressure perfectly normal. The systolic is usually very low, so that the pulse pressure is anywhere from 15 to 20. This condition I have seen about once in every twenty or twenty-five cases of influenza under my care, and it has appeared in cases showing the very mildest or slightest degree of infection, as well as in the severer types. The fact that it appears in the mildest type of infection, in which the fever is very low and lasts only three or four days, as well as in the severer types, would lead me to believe that it is not due to an infection of the heart muscle itself, but rather to some disturbance in the factors that control the blood pressure.

It has been pointed out that severe infections, including influenza, frequently produce a disturbance of the suprarenal gland. For this reason I have used in all these cases the suprarenal gland or its extract, giving usually 10 drops of the 1:1,000 solution under the tongue every three hours. Within twenty-four hours there is usually a very decided change in the clinical condition of the patient. The dizziness and extreme depression are gone and the pulse rate increases from 10 to 15 beats per minute, the pulse pressure also increases, and within a few days the patient is comparatively well.

I do not mean to imply that myocardial or endocardial lesions do not occur, as they undoubtedly do in any such severe infection as influenza. However, I do feel that the majority of the heart manifestations we encounter are of the type described above.

S. R. Salzman, M.D., Toledo, Ohio.

HELPING PHYSICIANS WHO HAVE HELPED THE GOVERNMENT

To the Editor:—There have been a large number of physicians who have profited professionally by the work they have been assigned while in the government service, by virtue of having been given base hospital assignments, intensive instruction courses, etc. On the other hand there have been a very large number who have been assigned administrative work, field work, etc., which has caused their real professional value to a community to deteriorate while in the service. Since as the government has arrangements for giving intensive instruction at certain clinics, I believe it would be only fair for them to make this instruction available for those who have had no such opportunities during their active war service.

I understand that the provision for an extra month's pay from date of discharge will not apply to members of the Reserve Corps unless they are discharged on account of physical disability; also there has been no opportunity for them to take advantage of the month's vacation out of each year which accumulates for those holding permanent commissions. If these statements are correct, they are additional arguments in favor of the foregoing plan.

Please do not publish my name or address.

M. M. C.

QUALIFIED PHYSICIANS DESIRED IN FLORIDA

To the Editor:—There has been considerable criticism from time to time by men from other states because the medical laws of Florida do not permit of reciprocity in medical licensure. In justice to the people and the medical fraternity of Florida I wish to state that we would have no objection to reciprocity of medical licensure between other states and Florida if it could be restricted to high grade men who are graduates of our best medical schools. An examination of the records shows, however, that literally thousands of requests for reciprocity have been received by the secretary of the Regular Board of Medical Examiners of Florida, and that a very large percentage of these are from men who are graduates of low grade schools. Many letters show extreme illiteracy, stamping the writers as uneducated men. Some letters have been threatening.

Florida offers as good a field for qualified medical men as any state in the Union today. In fact, we urge and welcome high grade men to locate in Florida. The officers of the state medical society will gladly cooperate in placing men in suitable locations. The examinations are exceedingly fair and our medical associations growing stronger, with medical fellowship better than ever before. We urge and welcome men from high grade schools to come and locate in "the Land of Flowers."

Fred J. Walter, M.D., Daytona, Fla.
President, Florida Medical Association.

"THE 'ACRID PRINCIPLE' OF CERTAIN PLANTS"

To the Editor:—I note in The Journal, Dec. 7, 1918, p. 1917, an editorial comment on "The 'Acrid Principle' of Certain Plants." You cite the work of Brown and Anderson at the Pharmacological Laboratory of the University of Minnesota respecting the cause of acridity in certain plants. I called attention to the facts cited in the editorial in an article published in *Science,* 1903, **18,** 115. My attention was called to the matter by Mr. W. E. Safford, botanist in the Bureau of Plant Industry. He said that he had heard it stated that the acridity of certain plants mentioned, such as the *Colocasia* and *Arisaema triphyllum,* was due to this cause, and requested that I have an examination made of them. As described in the article mentioned, I turned the matter over to Mr. B. J. Howard, microscopist of the Bureau of Chemistry. Soon after beginning the examination he came to me in quite an excited manner and asked me to witness a most peculiar phenomenon. In the field of the microscope I saw some oblong objects, not unlike extremely attenuated balloons of the Zeppelin type. In a short time I saw a sharp arrow discharged from one of these bundles, producing a slight recoil in the balloon. Soon thereafter a number of arrows were discharged simultaneously, the arrows going quite a distance in the field of the microscope and producing a corresponding recoil. It was, indeed, a true bombardment. The bundles of crystals (raphides) served as guns, and the slender sharp arrows of calcium oxalate were the missiles. It was truly a most remarkable display. It is easy to see how these extraordinarily sharp points discharged against the mucous surface produce the intense pain and irritation which the chewing of plants of this kind causes. Mr. Safford told me that among the Polynesians, with whom he had lived for a considerable length of time, these calcium oxalate bearing plants are some of the principal foods. They have to be well cooked before they are eaten. The cooking probably dissolves the crystals, and the plants are then eaten without injury or irritation. The *Colocasia* is the food product generally employed. If the Indian turnip, *Arisaema triphyllum*, is pulverized and the juice expressed and placed in the mouth, no sensation of acridity is experienced. This indicates either that the crystals of calcium oxalate are not expressed with the juice, or else that they do no harm unless shot out of the little cannon. The article in *Science* ends with this paragraph:

---

[1] "Lung Germine," a fraudulent consumption cure was exposed by the Propaganda department of The Journal some years ago. The matter appears in the pamphlet, "Consumption Cures," published by the American Medical Association, price 20 cents.

> While not fully established, there is presumptive evidence that the pricking and burning sensation experienced in masticating materials of this kind is mostly of a mechanical origin.

H. W. Wiley, M.D., Washington, D. C.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will *not* be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DEATHS FROM INFECTIOUS DISEASES

To the Editor:—Please give the numbers of deaths during the last five years in the United States from phthisis, pneumonia, scarlet fever, measles, whooping cough and diphtheria.

J. M. Mitchell, M.D., Pontiac, Ill.

Answer.—Figures are available only for the registration area of the United States, which, in 1916—the year for which the latest statistics are published—comprised twenty-six states and represented 71,621,632 people, or 70.2 per cent. of the total population of the United States. The figures in the following tabulation are from mortality statistics published by the Bureau of the Census of the U. S. Department of Commerce:

DEATHS IN REGISTRATION AREA OF UNITED STATES, 1911-1916 *

Communal Infections.—During last year Dr. D. C. Kirkhope, M.O.H., found it necessary to draw the attention of the Tottenham education committee to the increased prevalence of, what he designated, "communal" diseases since the outbreak of the war, and he ventures the opinion that they were largely due to soldiers returning from camps and from the front. He continued: Ringworm of scalp and body, impetigo, verminous conditions, scabies and such like unpleasantly preponderate among our minor ailment clinic cases, and it becomes increasingly important that teachers, attendance officers and nurses responsible for the scrutiny of children in schools, and the attendance of children at school, refer all children concerning whom they have the slightest doubt to the clinic for an expert opinion.—*The Medical Officer.*

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: *Montgomery, Jan. 14.* Chairman, Dr. S. W. Welch, Montgomery.

Arizona: Phoenix, Jan. 7. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

Colorado: Denver, Jan. 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

District of Columbia: Washington, Jan. 14-16. Sec., Dr. *Edgar P. Copeland, The Rockingham,* Washington.

Hawaii: Honolulu, Jan. 6. Sec., Dr. J. R. Judd, Honolulu.

Kansas: *Topeka, Feb. 11.* Sec., *Dr. H. A.* Dykes, Lebanon.

Minnesota: Minneapolis, *Jan. 7-10.* Sec., *Dr.* Thomas McDavitt, 741 Lowry Bldg., St. Paul.

Missouri: St. Louis, Jan. 28-30. Sec., *Dr. G. H. Jones,* State *House, Jefferson* City.

New Mexico: Sante Fe, Jan. 13. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: Jan. *28-31.* Albany, Buffalo, New York City and Syracuse. *Mr. Herbert J. Hamilton, Asst. Prof.* Exams., New York Dept. of Education, Albany.

North Dakota: Jan. *7.* Sec., Dr. G. M. *Williamson,* 860 Belmont Ave., Grand Forks.

Oklahoma: Oklahoma City, Jan. 7-8. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, Jan. 7. Sec., Dr. H. S. Nichols, Corbett Bldg., Portland.

Pennsylvania: Philadelphia, Jan. *7-9.* Sec., *Mr.* Nathan C. Schaeffer, State Capitol, Harrisburg.

South Dakota: Pierre, Jan. 14. *Sec., Dr. P.* B. Jenkins, Waubay.

Utah: Salt Lake City, Jan. 6. Corres. Sec., Dr. G. F. Harding, 405 Templeton Bldg., Salt Lake City.

Vermont: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

Washington: Spokane, Jan. 7-9. Sec., Dr. C. N. Suttner, 415 Old Nat'l Bk. Bldg., Spokane.

Wisconsin: *Madison,* Jan. 14. Sec., Dr. J. M. Dodd, 220 E. 2d St., Ashland.

MEDICAL SCHOOLS OF MEXICO AND CENTRAL AND SOUTH AMERICA

From the following medical schools of Central and South America replies to questionnaires have been received by the Council on Medical Education which furnish a fair idea of the character of these institutions. *Statements in regard to* them are as follows:

Argentina

Faculty of Medical Sciences of Cordoba, *Cordoba,* Argentina.—Organized in 1878. Completion of the six-year course of the secondary school admits to the medical course. The latter covers seven years; physics, chemistry and biology being given in the first two years. The faculty consists of 40 professors, 10 of whom are said to devote considerable time to scientific research work. There are also 34 instructors, or a total of 74 teachers. The institution has access to 350 beds in a hospital adjoining the college building, in connection with which also there is an outpatient department. Attendance is required at 30 necropsies, and the seniors are said, on the average, to attend about 20 maternity cases. There is a medical library having over 5,000 volumes, and from 60 to 70 medical periodicals are regularly received. There is a nucleus for a medical museum, but this has not been developed. The students enrolled are: first year, 90; second year, 81; third year, 75; fourth year, 63, and fifth years, 49, a total of 358.

Faculty of Medical Sciences of the University of Buenos Aires, Buenos Aires, Argentina.—Year of organization not given. Graduation from the six-year course in the secondary school admits to the medical course, which covers seven years. Premedical sciences are given in the first two years of the medical course. The faculty consists of 68 teachers, devoting on the average 3 hours per week to teaching besides the practical work. The usual laboratory courses of instruction are given. The college has access to 420 hospital beds and also to a dispensary said to have 15 consultation rooms and an average of about 500 patients daily. Students are required to witness postmortems in the hospital, there being altogether about 200 necropsies each year. Each student, also, must have attended at least 4 maternity cases. The college has a library of 48,000 volumes, including a full supply of medical periodicals. There is a medical museum containing nearly 6,000 anatomic and pathologic specimens. The students enrolled are: first year, 717; second year, 681; third year, 573; fourth year, 431; fifth year, 277; sixth year, 204; seventh year, 168, a total of 3,051. From the standpoint of student enrolment this is the largest medical school in the Western Hemisphere, as far as reports have been received.

Bolivia

FACULTY OF MEDICAL SCIENCES, LaPaz, Bolivia.—Founded in 1830 but not completed until 1835. Its first dean was Dr. Pasamanos. Completion of the secondary school course admits to a seven-year course in medicine. The premedical sciences, physics, chemistry and biology, are given in the first two years of the medical course. There are 19 professors who give, on the average, about 12 hours per week to research work. The medical school has access to 365 hospital beds. There is in connection with the hospital an emergency department, a municipal consultation office and an office of vaccination caring for about 55 patients per day on the average. Attendance on postmortems is required of medical students, as is true also of maternity cases, although figures are not given. The library consists of 399 volumes, but no medical periodicals are received. There is no medical museum. The students enrolled are: first year, 23; second year, 8; third year, 9; fourth year, 8; fifth year, 14; sixth year, 5; seventh year, 2, a total of 69. The institution also gives courses in pharmacy, chemistry and midwifery.

Brazil

FACULTY OF MEDICINE OF PORTO ALEGRE, Porto Alegre, Brazil.—Organized and equipped by the government of Brazil in 1898. Eleven years of elementary and secondary education precede admission to the medical school, the latter having a six-year course. Premedical sciences, physics, chemistry and biology, are given in the first year of the medical course. The school has 34 professors giving, on the average, one hour per day to scientific research work. The institution has laboratories in physics, chemistry, anatomy, legal medicine, physiology, histology, hygiene, pharmacology and microbiology. The school has access to about 200 hospital beds and to a dispensary having about 30 patients per day on the average. There are very few postmortems. No fixed number of maternity cases is required of the students. The library has about 3,200 volumes, but only 5 medical periodicals. There is a medical museum having altogether 163 prepared specimens. Students enrolled in 1917 were: first year, 29; second year, 50; third year, 29; fourth year, 15; fifth year, 27; sixth year, 29, a total of 179.

Colombia

UNIVERSITY OF CARTAGENA MEDICAL FACULTY, Cartagena, Colombia.—Founded in 1828. Completion of the six-year secondary school course giving the degree of Bachelor of Technic is required for admission to the six-year medical course. The premedical sciences, physics, chemistry, and biology are given in the first two years. The school has 19 professors who give 3 hours daily to scientific research work. The school has access to only 30 hospital beds and has a small dispensary of only 10 patients per day on the average. The students are said to assist at from 2 to 4 necropsies a year. No definite number of maternity cases is required. The library is said to consist of only 40 volumes and 4 medical periodicals. There is a small museum of natural history, but it contains no anatomic and pathologic specimens. The students enrolled in the medical school in 1917 are: first year, 9; second year, 3; third year, 5; fourth year, 7; fifth year, 5; sixth year, 10, a total of 39.

Mexico

SCHOOL OF MEDICINE OF DE NUEVO LEON, Monterey, Mexico.—Founded in 1859. Completion of the work in a superior secondary school admits to the five year medical course. The courses in physics, chemistry and biology are required to have been completed before admission to the medical course. There are 18 professors, each said to devote about two and a half hours per day, on the average, to teaching. The school has access to 127 hospital beds and to a dispensary having an average of about 14 patients per day. Attendance at necropsies is obligatory. Each student must have attended, as a minimum, 10 maternity cases. The medical library contains only about 350 volumes, and there are only 2 medical periodicals. There is a small medical museum containing about 35 anatomic, 11 pathologic and 45 other specimens. In 1917 the students enrolled were: first year, 9; second year, 4; third year, 3; fourth year, 4; fifth year, 2, a total of 22.

SCHOOL OF MEDICINE AND PHARMACY OF YUCATAN, Yucatan, Mexico.—Organized in 1833. Completion of the 12 grades of preliminary instruction, including work in the secondary (superior) school, is required for admission to the six-year medical course. Physics, chemistry and biology are required to have been completed in the superior school before admission to the medical course. The school has 25 full-time teachers giving, on the average, two hours daily to scientific research work. Laboratory courses are given in clinical chemistry, histology, anatomy, pathology, bacteriology, parasitology and therapeutics. The school has access to 600 hospital beds, but there is no outpatient department. It is said that there are about 300 necropsies per year, and attendance by the students is required. Students are required to attend at least 5 maternity cases. The library is said to consist of 3,000 volumes and 4 medical periodicals. A museum contains 1,727 anatomic and pathologic specimens. The students enrolled in 1917 are: first year, 17; second year, 16; third year, 18; fourth year, 9; fifth year, 6; sixth year, 4, a total of 70.

SCHOOL OF MEDICINE OF THE STATE OF MICHOACAN DE OCAMPO, Morelia, Mexico.—Organized in 1828. Graduation from the secondary school admits to the five-year medical course. Physics and chemistry are required to have been completed in the first year of the medical course and biology in the second year. There are 12 professors who devote on the average 2 hours per day to scientific research work. Laboratory courses are given in physics, chemistry, biology, mineralogy, geology, anatomy, physiology, microbiology, histology, pharmacy and history of obstetric drugs. The medical school has access to 400 hospital beds and has a dispensary of 80 patients per day on the average. There are about 150 necropsies each year and about 350 maternity cases. The library consists of 2,000 volumes and 8 medical periodicals regularly received. A small museum containing 113 anatomic and pathologic specimens has been established. The numbers of students enrolled in 1917 are: first year, 10; second year, 8; third year, 8; fourth year, 12; fifth year, 7, a total of 45.

SCHOOL OF MEDICINE AND PHARMACY OF GUADALAJARA, Guadalajara, Mexico.—The University of Guadalajara, including its faculties of law, medicine and theology, was established in 1792 by royal order of the King of Spain and the Indies. The preliminary education consists of six years of elementary and five years of secondary education, which admits to the medical school. In 1916 the medical course was extended from five to six years. Physics, chemistry and natural sciences are required to have been studied in the secondary school, which has two large laboratories. The first year of medicine includes courses in medical physics and biologic chemistry. There are 32 professors who devote from 3 to 6 hours per week to teaching. Laboratory courses are given in physiology, bacteriology, normal and pathologic histology, organic chemistry, inorganic chemistry and general chemical analysis, electrotherapeutics and clinical diagnosis. Attached to the school of medicine is the Civil Hospital having 800 beds, of which 300 are devoted to teaching purposes. Connected with the hospital is a dispensary or polyclinic caring for about 50 patients per day on the average. Students are compelled to attend postmortems two or three times per week and there is an ample supply of material. Each student is required to attend at least 10 maternity cases during his sixth medical year. The library contains 1,000 volumes, with a large list of foreign medical periodicals. On account of the unsettled conditions in Mexico, the school has been able to receive regularly only about 15 or 20 of these periodicals. A medical museum is being developed, and about 40 or 50 anatomic specimens were collected during the last year. Students enrolled in 1917 are: first year, 37; second year, 35; third year, 31; fourth year, 21; fifth year, 21; sixth year, 5, a total of 150. The departments of pharmacy and midwifery have enrolled, respectively, 12 and 8 students.

NATIONAL SCHOOL OF MEDICINE OF MEXICO, Mexico City, Mexico.—Organized in 1833. Eleven years of preliminary education are required, including 5 years in the superior school, which corresponds with the high school course in the

United States. The medical course covers six years, which includes the courses in physics, chemistry and biology. The college has 50 professors. Laboratory courses are given in histology, pharmacy, pathologic anatomy, biologic chemistry, microbiology and physiology. The number of hospital beds available is not given. It is stated that no record is kept of the outpatients in the dispensary. Students taking the course in pathologic anatomy are required to attend two postmortems during the year. There is no fixed number of maternity cases. The library contains over 10,000 volumes with a large supply of medical periodicals, which have not been regularly received recently owing to war conditions. There is a medical museum containing nearly 2,000 anatomic and pathologic specimens. The students enrolled during the year of 1917 are: first year, 215; second year, 140; third year, 45; fourth year, 62; fifth year, 39; sixth year, 35, a total of 536.

San Salvador

Medical School of San Salvador, San Salvador, Central America.—Organized in 1903. A certificate of preparatory professional education is required for admission to the six-year medical course. Physics, chemistry and biology are included as a part of the medical course. The school has 20 professors devoting from three to six hours per week to scientific research. Laboratory courses are given in histology, parasitology, bacteriology, biologic chemistry and toxicology. There are 120 hospital beds devoted to teaching purposes and a dispensary having about 40 patients per day on the average. Attendance at postmortems is not required, and no minimum number of maternity cases has been fixed. The library consists of approximately 1,500 volumes and only 3 medical periodicals. There is no medical museum. The numbers of students enrolled are: first year, 22; second year, 10; third year, 6; fourth year, 9; fifth year, 9, a total of 56 students in 1917.

Book Notices

The Doctor in War. By Woods Hutchinson, M.D. Cloth. Price, $2.50. Pp. 481, with illustrations. Boston: Houghton, Mifflin Company, 1918.

The author is well known as a writer for the public on medical topics, and most of the chapters in this book have previously appeared in magazines and syndicated newspaper articles. In his capacity as a journalist, Dr. Hutchinson visited the medical departments of the various forces in the great war, spending practically a year during 1917 in interviewing leaders and making observations. His book will give the reader a good picture of medical conditions with the fighting forces. The author seems to be hyperenthusiastic as to medical accomplishments during the war, and seems especially prone to accept too readily first estimates on new procedures or methods. There have already been many books on the medical aspects of the war written for lay readers. As a piece of descriptive work, the book by Dr. Hutchinson ranks with the best. As a basis for judgment of scientific accomplishments, it cannot be given equal rank.

Benjamin Rush and His Services to American Education. By Harry G. Good, Ph.D., Professor of Education, Bluffton College. Cloth. Price, $1.60. Pp. 283. Bluffton, Ohio: American Educator Company, 1918.

Benjamin Rush was a many-sided physician; there have been many books concerning his life and work in addition to numerous papers and a voluminous correspondence which he himself prepared and which have been well preserved in various places. The book by Professor Good is concerned primarily with the work of Dr. Rush in education and social reform. The first few chapters discuss his early life and his work as a statesman and as a physician. The fourth and fifth chapters concern "Benjamin Rush and Dickinson College" and "The Educational Writings of Dr. Rush." An appendix contains a rather comprehensive bibliography. Professor Good has not overstated the accomplishments of Dr. Rush. The plain recital of facts indicates that a statement commonly made today concerning busy men applied very aptly to Benjamin Rush: The busiest men are those who seem to have the most time for doing things.

Medicolegal

Restrictions on the Physical Examination of Plaintiffs

(*Perkins v. Monongahela Valley Traction Co. (W. Va.), 95 S. E. R. 797*)

The Supreme Court of Appeals of West Virginia says that the right to have a physical examination of a plaintiff in an action to recover damages for personal injury, if such right exists, and on this the court expresses no opinion, can certainly only be reasonably exercised. The authorities on the question of the existence of the right are irreconcilably in conflict. An examination of the authorities leads to the conclusion that even in those jurisdictions in which the right to have such physical examination is recognized, it is granted or withheld by the court in the exercise of a sound judicial discretion. The things to be considered by the court in passing on a motion for a physical examination are the convenience of the plaintiff, the necessity for the physical examination, that is, the probability that it will produce evidence of value in the trial of the case, and also whether or not the plaintiff has declined to submit to such reasonable examination. In no case have the courts required the submission to a physical examination that would result in serious inconvenience to the plaintiff, or would involve a surgical operation, and ordinarily the plaintiff in such case is allowed the privilege of having such examination conducted at such time and place as he desires, in case he makes a reasonable selection thereof. The purpose of such physical examination in those jurisdictions in which it is allowed is not to secure evidence to defeat the plaintiff's case, but to expose the true situation; and should such examination result in opinions on the part of the examining physicians adverse to the defendant, he should not be allowed to have another examination with the hope of securing opinions from other experts favorable to him. When the plaintiff permits voluntarily such examination, the defendant should then select the experts he desires to make it, and should not be allowed to embarrass or inconvenience the plaintiff by unnecessary repetitions of such request. It is true that ordinarily such examinations are made in private; but this is because of the embarrassment that it might cause the plaintiff to submit to a public exposure of his person. If he prefers to have the examination made in the presence of the jury, the defendant cannot object, and certainly the testimony of the experts would be very much more enlightening under such circumstances than it would be when the object being examined was not physically presented to the jury along with the expert testimony. With reference to this particular case, the court holds that it is not an abuse of discretion to refuse to require the plaintiff in a suit to recover damages for personal injuries to submit to a physical examination, to be conducted by physicians selected by the defendant, when it appears that the plaintiff has submitted to one such examination, and on demand being made for a second one, expressed his willingness to submit thereto at the trial, if indeed the court has the power to require such examination in any case.

Bases for Convictions of Illegally Practicing Medicine

(*State v. Wild (Mo.), 202 S. W. R. 613. State v. Evertz (Mo.), 202 S. W. R. 614. State v. Evertz (Mo.), 202 S. W. R. 616*)

The St. Louis Court of Appeals, in these three cases, which are "not to be officially published," affirms convictions of the defendants of practicing medicine without a license.

In the first case, the court holds that the information was not fatally defective in failing to allege that the defendant was not a commissioned surgeon of the United States Army, Navy, Public Health, or Marine Hospital Service; neither in failing to allege that the defendant was not authorized to practice in Missouri under a "permit" of the state board of health, nor in failing to allege that the defendant had no license issued to him by virtue of the laws of another state or territory. It was argued that the information was fatally defective in that it did not allege that the defendant did treat or attempt to treat the sick; but, while it did not charge the offense in the language of the statute, it was sufficient in charging that the defendant "did treat and attempt to treat one G. E. Wetzel for a disease known as rheumatism," thereby substantially charging that the defendant treated or attempted to treat "the sick or others afflicted with bodily or mental infirmities," in violation of the statute. The evidence disclosed that Wetzel was an employee of the health department of the city, presented himself at the defendant's office stating that he came because he had rheumatism and asking the defendant whether he could cure it; that the defendant said he could cure him "in different ways, . . . by way of massage, by electricity or water"; that the defendant undertook to treat him by rubbing him, and by the use of an electric battery, and by the application of water, for which the defendant charged and was paid $2. Wetzel testified that he had in fact no rheumatism; that he was perfectly well at the time, so far as he knew; and that he thus called on the defendant and submitted himself to the defendant for the purpose of making a case against him. The court regards it as clear that the conduct of Wetzel was not of such character as to relieve the defendant from the consequences of his acts done in violation of the statute, the evidence showing that the defendant had offices consisting of certain rooms, with appliances for treating patients, and that the prosecuting witness merely gave him the opportunity to demonstrate that he was treating, or attempting to treat, the sick or those afflicted. Nor was the evidence insufficient to sustain a conviction because the witness admitted that he had no rheumatism at the time in question, for the defendant attempted to treat the sick or afflicted.

In the second case, wherein it was said that it did not appear by the evidence that the state board of health was legally constituted, the court answers that the statute, of which the court takes judicial notice, provides for the creation of the board of health and defines its powers, and there was evidence in the case sufficient to show that under this law a state board of health was acting in the state. The treatment in this case consisted in the defendant's passing his hands over Wetzel's forehead and breathing on the knee in which Wetzel said he had rheumatism, and directing his attention to pictures on the wall, saying: "You get better; you get better; you are getting better," this being what the defendant called "mental suggestion." It was in evidence also that the defendant had advertised himself to give healing to the sick and afflicted by his method of "autosuggestion," as he called it, and held himself out as a doctor of "suggestive therapeutics," signing his name with the initials "S.D.," meaning Doctor of Suggestive Therapeutics.

In the third case it is held that an information following the language of the statute in charging the offense was sufficient. It is also held that the evidence showed a violation of the statute by showing that the defendant maintained an office, with a sign: "Evertz School of Suggestion. Oscar Evertz, S.D., Suggestionist. Treatment. Instruction"; that he circulated advertising matter; offered to treat a case for a certain sum, etc.

Valid Law and Revocation of License

(Lanterman v. Anderson et al. (Calif.), 172 Pac. R. 625)

The District Court of Appeal of California, Second District, affirms a judgment which affirmed the proceedings and determination of the board of medical examiners of the state under and by which the certificate and license authorizing petitioner Lanterman to practice medicine and surgery was revoked on the ground that he had been guilty of unprofessional conduct as defined by the state medical act, namely, the procuring or aiding or abetting or attempting or agreeing or offering to procure a criminal abortion. The court says it was argued that because the statute refers to a "criminal abortion," and that because in order to determine what a criminal abortion is one must look to the penal code, the charge would be insufficiently laid unless the acts defined in the penal code as constituting the crime of abortion were set forth. But the petitioner was not charged with a crime, nor was he subject, on the adverse determination made, to any penalty except the revocation of his license to practice medicine and surgery, and it must be said that the language of the statute is sufficiently explicit to advise a person charged thereunder of the particular kind of unprofessional conduct which it is proposed to prove against him, and that is all that need be said on the question. Nor does the court agree with the contention that the act under which the petitioner was prosecuted is unconstitutional on the ground that powers are conferred which belong strictly under the constitution to the judicial department. Acts of the nature here under consideration have been repeatedly sustained as a proper exercise of the legislative grant. The hearing in the lower court being on a writ of certiorari or review, that court did not err in refusing to take testimony on whether one member of the board had absented himself during the taking of evidence, because the record showed that a quorum of the board was present, and the writ of certiorari may not be used to add to or modify a record with respect to any jurisdictional fact determined therein. It was contended that there was no legal or sufficient evidence authorizing the medical board to make the order complained of. The force of this objection rested chiefly on the assertion that all the material testimony furnished against the petitioner was that given by his accomplices. But, the action not being criminal in its nature, the statutory mandate that a person may not be convicted on the uncorroborated testimony of an accomplice had no application. This court feels satisfied that any witness whose testimony as to competent facts was convincing to the board engaged in the hearing of the charge would be legally sufficient.

Eccentricities and Business Capacity of an Epileptic

(Furlong et al. v. Tilley et al. (Utah), 172 Pac. R. 676)

The Supreme Court of Utah affirms a judgment upholding the validity of a deed to land executed to his sons some four years before his death by a man who was subject to epileptic fits, which occurred generally about once a month, sometimes twice a month in later years, during which fits and for a short time after which it was admitted he was incapable of transacting business. The court says that it believes it is a matter of common knowledge, of which the court will take judicial notice, that when a person is so afflicted to the extent appearing in the record in this case, he is not necessarily disqualified from transacting ordinary business during the intervals between the attacks. This, perhaps more than anything else, accounted for the apparent conflict in the opinions of the various witnesses. Those who happened to see the grantor in one of these attacks or soon after would notice something abnormal in his demeanor or conversation, while those who saw him only in the intervals would notice nothing unusual. It did not appear from the evidence that the eccentricities enumerated, introduced to show the grantor's incompetence, reflected his mental condition at all times. They appeared to be more in the nature of isolated occurrences of mental aberration. As to the incidents themselves, while many of them were exceedingly peculiar, they were not by any means conclusive. His going to town in a buggy and returning without it, unexplained, certainly indicated absence of mind. His trying to put on baby shoes, perhaps in the presence of his little grandchildren, might be only for their amusement, or it might indicate mental aberration at the time. His sitting on the curb and putting his feet in the ditch to cool them off was not unnatural or abnormal; it might not have been according to ethics under the circumstances. His wandering around at times through the town might or might not indicate abnormality. His saying to a Democrat in argument that "God would take care of the Republican party" may have suggested to the Democrat the rankest kind of imbecility; but this court as a whole cannot accede to that view. His failure on some occasions to remember names or persons with whom he was familiar is, perhaps, a common failing of many persons as they advance in years. This court cannot say that such evidence is even persuasive that such persons are incompetent to transact ordinary business. On the other hand, all the evidence in the record relating to the transaction itself indicated that at the time the deed was executed the grantor was in a normal state of mind.

Society Proceedings

COMING MEETINGS

Southern Minnesota Medical Association, Mankato, Jan. 20-21.

AMERICAN PUBLIC HEALTH ASSOCIATION

Forty-Sixth Annual Meeting, held in Chicago, Dec. 8-11, 1918

(Concluded from page 2177)

Program of the United States Public Health Service

Surg.-Gen. Rupert Blue, U. S. Public Health Service, Washington, D. C.: I would point out the need of special vigilance on the part of health authorities in order to prevent the introduction and spread of dangerous epidemic diseases by our returning soldiers. When the history of the present war is written, not the least significant part will be that which records the achievements in the field of preventive medicine. Hundreds of thousands of lives have been saved as a result of the excellent work in sanitation and preventive medicine carried on by the British, French and American military forces.

What can be done among soldiers in the unfavorable environment of war can and should be done among the civilian population in the more favorable environment of peace, and this can be accomplished by intensive health work carried on by the U. S. Public Health Service in cooperation with state and local authorities. The Public Health Service contemplates constituting itself a national center and clearing house for information, advice and educational assistance on all matters relating to public health and hygiene.

The National Welfare

Col. Victor C. Vaughan, Washington, D. C.: The government should assume control of certain functions of the educational system of the country. The youth of the country on reaching a certain age, to be determined after mature deliberation, should be drafted into the service. The only exemptions from this service should be the mentally incompetent. Those suffering with physical defects should be classified, their defects repaired so far as possible, and the training adapted to their individual needs. The period of training should cover two years, continuous or broken into terms. This training should be disciplinary, and to this extent military; but the primary and principal purpose should be the preparation of men, not for the fighting line, but for good citizenship. This service will be best administered under the War Department. The training should include the physical, mental and the moral man.

Physical development and the practice of personal and community hygiene should be one of the fundamentals. Instruction in the prevention and eradication of infectious diseases should be given by practical demonstration as well as by textbooks and lectures. Personal hygiene must be practiced in daily life. It is largely a matter of habit.

The English language must be taught, and its correct use demanded of all at all times. The history of our nation, its relation to other nations in time of peace and in time of war, its material resources, and its ideals, should hold an important position in the curriculum. The obligations and duties of citizenship should be impressed on all. To those lacking training in mathematics, physics, chemistry and biology proper instruction should be given.

Every individual should be given a substantial start in some industrial trade or profession. He should know how to take care of his own body, make a decent living, be a clean and intelligent citizen, and be ready at all times and under all conditions to render effective service to his country. These training schools should be without expense to the individual. He should be housed, clothed, fed and instructed by the government, and his family should be moderately compensated for his time. In fact, he should have the status of an enlisted man in the Army.

When he completes the courses at the training school he should pass into a reserve corps and should carry a qualification card showing his grades in physical, mental and moral fitness. In the reserve corps he should be examined at intervals of two years until he reaches 45 years of age. At these examinations his qualification card should be reviewed.

In addition to the service provided for above, the government should improve the efficiency and extend the functions of its health service. The registered area should be extended so as to embrace the whole country. Morbidity statistics should be collected on uniform cards. The hygienic laboratory of the Public Health Service should be developed, and opportunity should be given for the multiplication of research investigations. Both preventive and curative medicine should be placed at the service of all citizens socialized. Every community should have a health commissioner and such personnel as may be necessary, with hospital and laboratory adjuncts.

Venereal Disease Control

Dr. John Dill Robertson, Commissioner of Health, Chicago: Chicago secured an ordinance requiring the reporting of venereal diseases, June 29, 1917, the ordinance being practically in the form of the Australian law. It requires that the physician must report all cases of gonorrhea, syphilis and chancroid; the physician must give the patient an educational circular; in case the patient changes physicians, report must be made to the previous physician, and failure to continue treatment must be reported to the health department in ten days. In the first ten months of 1918, 6,258 cases of venereal disease were reported to the department. Known prostitutes are arrested by the police and brought to the Iroquois Memorial Hospital for the purpose of securing specimens for examination. When brought into court the women obviously guilty of crime are sentenced to the house of correction; others found infected are turned over to the health department and sent to the Lawndale Hospital. Of 480 males admitted to the house of correction in November, 1918, 6.25 per cent. were suffering with venereal diseases; and of the females, 11.6 per cent. I think it safe to say that not more than 1.5 per cent. of the population of Chicago is suffering with infectious venereal diseases. A municipal venereal disease clinic is essential for the enforcement of a venereal disease ordinance. At the Chicago clinic 630 men and ninety-one women were treated from Jan. 1 to Nov. 1, 1918.

A municipal venereal disease hospital is another essential. During the first ten months of 1918, Chicago treated 325 women between the ages of 15 and 53 in such a hospital. These women were kept occupied at such work as they were capable of doing. Statistics were obtained as to mental condition, educational status and occupations claimed by them. Morphin users were given treatment. Thirty-nine per cent. of these women had hooded clitoris, which suggests a possible predisposing cause for delinquency. Laboratory findings on specimens from patients showed 159 with syphilis positive; 127 with gonorrhea positive; 12 with mixed infection, and 27 nonvenereal.

Quack advertisements to the number of 1,500 were removed in Chicago, and 3,500 educational posters substituted. Druggists were educated against counter prescribing. With the absolute and full cooperation of the physician and the druggist, venereal disease can be controlled as effectively as tuberculosis.

Lipovaccines

Col. Eugene R. Whitmore, Washington, D. C.: In the U. S. Army, a number of lipovaccines have been prepared. The triple lipovaccine is now the official vaccine. A pneumococcus lipovaccine is also being used. Meningococcus, dysentery, cholera, plague and streptococcus lipovaccines have been prepared and tried out. The lipovaccines have the advantages that the entire amount of bacterial material can be given at one dose, without severe general reaction; and the immunity response is at least as good as when the bacterial material is given in divided doses suspended in saline solution. The lipovaccines keep for at least eight months. These advantages are of importance in public health work. The lipovaccines are probably not adapted to use in therapeutics. It is necessary to guard against attempting to adapt the advantages of the lipovaccines to the preparation of shotgun vaccines.

Industrial Disease Administration at the Present Time

DR. EMERY R. HAYHURST, Columbus, Ohio: Several important problems are at hand in adjusting health administration to cover industrial diseases and hygiene. There are: (1) keeping the workers able to work; (2) providing for increasing numbers of women, older people and youths; (3) maintaining all sanitary regulations; (4) watching especially against fatigue; (5) not only maintaining average vitality but raising the average vitality; (6) counteracting the indifference promoted by personal prosperity, number of available jobs, etc., and (7) continuing the spread of fundamental information calculated to save human waste—so-called hygiology. One establishment in Ohio, employing over 5,000 women, increased its output 10 per cent. almost over night by giving heed to advice from the state department of health on temperature and humidity control in the workrooms, and at the same time cut down, remarkably, absences, quittings and a peculiar form of illness that was spreading through the plant.

Shortage of hygienists and sanitarians to meet the demands is acutely felt, and it is necessary for certain properly equipped schools or the U. S. Public Health Service to select and instruct by short courses a large number of engineers, sanitarians and physicians in the principles of industrial hygiene and diseases.

Modern Advertising and the Nostrum Evil

DR. ARTHUR J. CRAMP, Chicago: The evils connected with the sale of medicinal preparations of the home remedy type—the so-called "patent medicines"—are due to proprietorship and to the advertising methods that such proprietorship engenders. The perpetual proprietary monopoly which the "patent medicine" seller obtains by means of our trade-mark laws makes extensive advertising profitable and, together with secrecy of composition, has led to the gross abuses that have made the "patent medicine" business a menace to the public health. Modern advertising differs from its earlier prototype in that whereas the latter chiefly, if not exclusively, notified the public simply where and how its demands might be supplied; the former is based largely on the principle of creating demands for the products advertised. No man has any moral right so to advertise as to make well persons think they are sick and sick persons think they are very sick. Such advertising is an offense against the public health. Modern medical advertising by the skilful use of testimonials, and by plausible claims, direct or inferential, leads the public to magnify every trivial ailment, deceives those who are well into the belief that they are sick, and impresses the idea that the products are panaceas for whatever ailments the public is suffering from or can be deceived into believing itself to be suffering from. Medicaments of the home remedy type for the self-treatment of simple ailments should contain no dangerous or habit-forming drugs; should not be recommended for diseases that are obviously too serious to be self-treated; should be nonsecret, and should not be sold under false claims or so as to make the public magnify trivial ills and dose itself unnecessarily. There are plenty of official products (U. S. P. and N. F.) to meet every legitimate requirement for medicaments for self-treatment. These products are nonsecret; their purity is established and protected by law. As any competent pharmaceutic house can make them, the elements of secrecy and proprietorship are removed and the incentive to fraudulent or misleading advertising claims is abolished.

Tuberculosis Control Following War Conditions

DR. D. B. ARMSTRONG, Framingham, Mass.: The war will undoubtedly increase the magnitude of the tuberculosis problem in the United States, just as it has in foreign countries. In 1913, the death rate from pulmonary tuberculosis in England and Wales was 101 per hundred thousand people living. By 1916 this had increased to 118 per hundred thousand. In Birmingham alone, for instance, the 1913 rate of 119 per hundred thousand had increased in 1917 to 130 per hundred thousand. As a result of the special tuberculosis work being done under the auspices of the National Tuberculosis Association in Framingham, we have in this community excellent evidence to show that tuberculosis exists in our civil population to a greater extent than had hitherto been supposed. In Framingham, which is a typical industrial town with average health conditions, there were on Jan. 1, 1917, twenty-seven known cases of tuberculosis. After an extensive search for tuberculosis, the number of living known cases was increased to 181 in November, 1918. An intensive examination of about two thirds of the population of this town has shown that approximately 2 per cent. of the people have tuberculosis in either an active or an arrested form. This means that in the United States as a whole there are 2,000,000 cases of tuberculosis, and at least 1,000,000 people who have the disease in an active and possibly contagious form.

How are we to meet this national problem? In the first place, it means adequate appropriations for general health and antituberculosis work. Where we have been spending 15 cents or 25 cents per capita on health work, we must spend from $1 to $2 per capita if we are going to meet our obligations. As to tuberculosis in particular, it is important to find the early cases and to get them under adequate treatment. The public at large must be educated more intensively than hitherto regarding the principles of hygienic living.

Work of the Department of Health and Sanitation of the United States Shipping Board

LIEUT.-COL. PHILIP S. DOANE, M. C., U. S. Army, Director of Health and Sanitation, U. S. Shipping Board Emergency Fleet Corporation: This department is maintaining supervision over the health of about 430,000 employees scattered over 7,000 miles of coast line. Like all war emergency industries, the Shipping Board had to organize its various departments in such a manner as to meet its needs. The problem confronting us was to secure such conditions in shipyards and their environment as to maintain the workers in the healthy, vigorous condition so essential to the speedy construction of ships. Arrangements are made with local hospitals for the care of injured employees. Yards employing more than 10,000 men without the nearby hospital facilities have their own hospital, constructed according to plans and specifications outlined by the Army, with suitable modifications.

The surgical care of injuries is given special attention. All employees are urged to report for dressing with every injury, no matter how slight; consequently the monthly reports show a percentage of injuries often running as high as 50 per cent. of the men employed. The board is cooperating with the Surgeon-Generals of the Army, Navy, and Public Health Service, and the Committee on National defense, in carrying on a prophylactic venereal campaign both in the shipyards and in the cities and towns surrounding them. This campaign is becoming so general in character that state laws are necessarily being enacted to favor this work.

The eradication of mosquitoes is an important measure at shipyards. This department cooperates with local and state health authorities to obtain suitable drainage of the yard and its environment, filling in low land, oiling stagnant water, etc. In mosquito countries, the screening of building and sleeping quarters is urged.

Owing to the efficient action of the medical and sanitary experts, not a single shipyard has been compelled to shut down during the influenza epidemic. It was strange that the Pacific Coast yards should have been affected before those of the Great Lakes region.

Team Work in Public Health

DR. GEORGE E. VINCENT, President of the Rockefeller Foundation, New York: The work of the fifty-seven health societies of the United States is to a large degree unsuccessful because too much time is spent in the collection of funds and preaching about accomplishments, thereby leaving no time for scientific investigation. It is certain that so long as the voluntary agencies of public health of this country persist in the present policy of isolation and rivalry, seeing their specialties out of focus, unconsciously misleading the public, hampering the development of unbiased research, and preventing the consistent and careful education of the people, they will be in no position to bring to bear on the federal government pressure for the creation of a federal department of health with a secretary in the President's cabinet. Three things are necessary to correct these evils: (1) the establishment of a definite body of scientific knowledge; (2) effective demonstration of the application of such knowledge, and (3) systematic, unified, consistent education of the public in the scientific basis of health and the principles of procedure.

Future State Policy in Relation to Health and Welfare

Mr. Frederick L. Hoffman, Newark, N. J.: A beginning has been made in this country through the Children's Bureau at Washington in initiating a plan for the systematic measurement of children of preschool age, subsequently, no doubt, to be followed by the introduction of systematic measurements of children during the teaching period from the primary grade to the university. The second prerequisite for a rational and effective public health administration is the accurate and complete registration of all serious illnesses, whether in private practice or in institutions under medical supervision and control. The third fundamental principle of modern health administration is a state medical service, including all the medical services now rendered in connection with public institutions, poor-law establishments, schools, state and municipal dispensaries, clinics of all kinds, etc.

Vaccination as a War Measure

Dr. Maurice Ostheimer, Philadelphia: Smallpox has increased during the war throughout the United States. In many instances the spread of the disease was definitely to be attributed to unvaccinated workers in the munition plants. In some instances a migrating unvaccinated worker developed smallpox and gave the disease to one or more workers in one, two or even three plants before he was caught and isolated. In Philadelphia alone up to Oct. 18, 1918, thirty-three cases of smallpox had been reported, while there had only been twelve during the year 1917 and only five in 1916. It might prove practicable for the U. S. Public Health Service to request of the U. S. Railway Administration that tickets for places outside of the city be sold only to a purchaser who presents certificates of successful vaccination for each member of his party.

Clinic for Vocational Diseases

Dr. Louis I. Harris, New York: Very few municipalities have done anything in industrial hygiene. This traditional idea that to do anything we must have elaborate outfit and budget has retarded progress in many communities of an industrial character. In New York City less than 200 cases per annum of occupational diseases were reported by all the 8,000 physicians, all the hospitals and dispensaries and all the industrial corporation physicians, an infinitesimal fraction of the number of cases that will subsequently be registered as tuberculosis cases, as cases of all kinds of occupational poisoning, and the things in which the occupational factor will never be recognized. The vocational clinic in New York gives to the poor men in the community, whom the health authorities are obligated to protect, protective medical care.

Closing Schools as a Means of Controlling Epidemic

Mr. Willard S. Small, Chairman, Bureau of Education: Fifty cities in thirty-one states were asked to give an opinion on this subject. Replies were received from thirty-two cities in nineteen states. An analysis of these replies shows that closure of schools as a means of controlling epidemics of the six diseases specified is unnecessary, unscientific and unjustifiable. The proper method of control involves a sufficient inspectorial force of physicians and nurses to maintain close supervision of cases and contacts; enforcement of isolation and quarantine under elastic administrative regulations; the employment of clinical and laboratory tests and reliance on such data; close correlation of the school medical inspection with the health department on the one hand, and with the school forces on the other hand, and continuous education of the public.

25 Important Points Relating to Surgical Treatment of Prostatic Hypertrophy. A. J. Ochsner.—p. 522.
26 *Ambulance Airship. N. W. Sharpe.—p. 526.

19. **Acidosis in Surgery.**—In the problem of shock exhaustion, the success of such restorative measures as oxygen, the intravenous injection of sodium bicarbonate with glucose and, above all, sleep—deep, untroubled sleep—Crile says, lends support to the laboratory conception that acidosis—intracellular acidosis—is the fundamental condition present in exhaustion from any cause.

21. **Quinin-Formaldehyd Solution in War Surgery.**—The claims made by Pilcher for this solution are that it is simple of preparation, stable, can be concentrated for transportation, the strength can easily be increased or diminished, and it can be used in an early stage of wound treatment, at the field or evacuation hospital. The solution is thus prepared: quinin sulphate, 1 gm.; hydrochloric acid, 0.50 c.c.; glacial acetic acid (99 per cent.), 5 c.c.; sodium chlorid, 17.50 gm.; aqueous solution of liquor formaldehydi, 1 c.c.; thymol, 0.25 gm.; alcohol (90 per cent.), 15 c.c.; water, q. s. ad 1 liter. (1) Dissolve the quinin in the hydrochloric and acetic acids. (2) Dissolve the sodium chlorid in the water. (3) Dissolve the thymol in the alcohol. Add No. 1 and No. 2, then the liquor formaldehydi (40 per cent), and finally the thymol solution. The solution is best applied as directed for the use of the Carrel-Dakin solution, or may be injected through the Carrel tubes every two hours, or more frequently, if necessary, to keep the wound bathed with it.

To test its efficacy it was employed in 100 cases of severely infected wounds at the American Red Cross Military Hospital No. 5, mostly compound comminuted fractures, which had been treated for from ten days to two weeks or longer with Dakin's solution, and in which the bacterial flora showed no signs of diminution in the great majority of instances. There was a marked drop in temperature and pulse in many cases on changing from Dakin's to quinin-formaldehyd solution, without any operative procedure. Some wounds showing a count of 10 to 15 bacteria per field apparently have been rendered free from germs within three days. That is to say, none have been found in the repeated examination of fifteen fields. Thirty consecutive cases treated within thirty-six to forty-eight hours after receipt of injury, on whom preoperative smears were made and the presence of infection established, were rendered sterile within forty-eight hours and have continued to show absence of any bacteria on repeated counts subsequently, with one exception.

24. **Radiolucent Semilunar Shadow Occurring in Cases of Intermittent Headache.**—As a cause for the appearance of this semilunar shadow, immediately below the cranial vault, as a constant factor in these cases, Miller and Williams offer the hypothesis that it is due to hydrostatic changes in the cerebrospinal cavity. The cases which have shown this shadow give parallel histories. All the patients entered the hospital for the relief of severe intermittent headaches, which do not respond to the usual methods of treatment. The four cases cited occurred in adults in middle life. Two of them were males, giving history of remote head injury, one of them nine years and the other twenty-seven years previous to entry to the hospital. Of the two females, neither had a history of injury. One was decidedly neurotic. All cases were free from gross anatomic disease or lesion. One male showed marked change in disposition, being considered by his family as dangerous on account of violent attacks of anger from trivial causes. This is the only suggestion of mental instability shown by any of the patients. Two deaths have occurred. One male, who was injured nine years previously, died from cerebral hemorrhage, and one female from a pulmonary lesion.

26. **Ambulance Airship.**—This ambulance was designed by Sharpe primarily for the welfare of the patient, his personal comfort, and his personal safety. No alteration of the streamline fuselage has been made, nor alteration of the fuselage that would involve a structural weakening; the requisite alterations are simple in design, inexpensive in material and labor, and well within the capability of the shop personnel of the flying field. The rear cockpit has been abolished, and a chamber developed within the fuselage for the carriage of a litter and a man, with a maximum clearance of 17 inches and a minimum of 14 inches. The usual turtle-back is unchanged, save that a stronger and more dependable locking device has been employed. Additional protection against the air (especially in case of pronounced shock) may be secured by clamping into place a translucent celluloid shield. The litter is essentially the service litter with but scant modification. Strong clamps, activating on the eccentric principle and attached to the longeron litter bed, engage in the litter longerons, which have been suitably metal-sheathed for their reception.

Boston Medical and Surgical Journal

27 *Blood Pressure in Insane Patients Aged Sixty and Over. E. T. Gibson and A. M. Kimberly.—p. 693.
28 Report of Hospital for Convalescents. W. H. Devine.—p. 696.
29 Speech-Reading for the War Deaf. C. J. Blake.—p. 697.

27. **Blood Pressure in Insane Patients.**—A careful blood pressure study was made by Gibson and Kimberly of 163 insane persons confined in an asylum. They found that diastolic pressures in both sexes vary little after 60. In men systolic pressures increase about 10 millimeters of mercury for each five years up to 75. Systolic pressures in women increase abruptly in the years from 65 to 69. In older women the pressure is less and does not vary with age. Both diastolic and systolic pressures are distinctly higher in women. About half of both men and women had evidence of cardiorenal disease. Blood pressures average the same in this group as in all the men and women. Blood pressures in men average the same in those with positive Wassermann reaction as in those with negative Wassermann reaction. The blood pressure is not affected significantly by the psychiatric diagnosis, except in senile dementia, in which the averages for both sexes are higher. One third of the women and one fifth of the men have systolic blood pressures over 180 mm. Evidence of heart and kidney disease was found in all but one of these men but in only two thirds of the women.

36 *Modification of Technic of Voges and Proskauer Reaction. G. C. Bunker, E. J. Tucker and H. W. Green.—p. 493.

30. **Medium for Enumeration of Colon-Aerogenes Group.**—Instead of depending on inhibition of certain species of bacteria, Ayers and Rupp believe that it is far better to simplify the culture medium to a point where the sources of nitrogen and carbon are in such a form as to allow only the growth of the organisms desired. With this view in mind, they have prepared a simple synthetic medium in which there is a single source of nitrogen, namely, sodium ammonium phosphate and a single source of carbon, namely, lactose. The composition of the medium is as follows: Solution 1: Sodium ammonium phosphate, 0.4 per cent.; acid potassium phosphate, 0.2 per cent.; lactose, 1 per cent.; dissolve in distilled water. Solution 2: Filtered solution of agar in distilled water, 3 per cent. Mix solutions 1 and 2 in equal proportions while hot and put up in definite amounts (100 c.c. or more) into flasks or bottles and then sterilize. A slight precipitate may appear on sterilization, but this does not interfere with the count and may not appear on the plate. At the time of plating, after the agar medium is melted and while at its highest temperature add for each 100 c.c. of medium 0.5 c.c. of a 1 per cent. alcoholic basic fuchsin solution and follow at once with 0.5 c.c. of a freshly prepared 5 per cent. sodium sulphite solution. Mix thoroughly and allow to cool, then pour into plates as usual. The red color is not entirely destroyed by the sulphite and at time of plating the medium is pink. The colonies appear on the plates as medium sized red colonies with a deep red ring around them. The color about the colony is quite characteristic, although some have only a deep red color in the colony itself. Bacteria which may also grow on the medium and which do not belong to the colon-aerogenes group usually give pink or uncolored colonies which can be distinguished readily from those of the gas formers.

31. **Endo Medium for Isolation of B. Dysenteriae.**—A mannite-glucose double sugar medium on the principle of Russell's double-sugar agar is described by Kligler and Defandorfer, to be employed for rapid differentiation of the Shiga and Flexner class of dysenteric bacilli.

36. **Technic of Voges and Proskauer Reaction.**—The authors claim that the use of 0.5 c.c. of a 45 per cent. solution of sodium hydroxid, Syracuse watch glasses, and 1 c.c. of the culture results in the development of a greater number of positive Voges and Proskauer reactions in a shorter interval of time than the method given in the latest (1917) edition of "Standard Methods of Water Analysis." An incubation period of two days at 30 C. is recommended in place of that of five days in order to obtain the maximum number of positive Voges and Proskauer reactions from glucose potassium phosphate broth. In order to avoid separate cultures for this test, 1 c.c. portions may be withdrawn from those incubated for the methyl red test.

37. **Feeding Experiments with Raw and Boiled Carrots.**—In the present food crisis, a knowledge of the dietetic properties of root vegetables is of importance, particularly so since the use of dehydrated vegetables promises to come into general vogue. With these considerations in mind, Denton and Kohman instituted feeding experiments with carrots, using albino rats. They found that carrots, when properly supplemented with starch, purified commercial casein, butter or lard, and salts, to such an extent that 50 per cent. of the caloric value of the diet is still derived from carrots, will produce normal growth and reproduction in albino rats. Carrots as an exclusive diet, except for the addition of calcium, phosphorus, sodium and chlorine, may support animals in apparently good health for as long as sixteen weeks. Although there is no growth, the animals on this diet may maintain and at times even increase their own body weight. Carrots contain a considerable amount of both the water-soluble and fat-soluble vitamins. Ordinary methods of cooking do not perceptibly injure the nutritive value of carrots, or certainly not when used as part of a mixed diet. However, a considerable portion of the caloric value of the food is lost when the water used in cooking is rejected.

38. **Creatinuria.**—Steenbock and Gross believe that creatin is an end-product in the catabolism of certain precursors in the protein molecule just as urea is of others. Creatin generally occurs in the urine in instances where there is an increased protein catabolism; namely, during fevers, in exophthalmic goiter, in tumor cachexia, in post partum resolution of the uterus, in hydrazine and phosphorus poisoning, and in diabetes mellitus. Creatin in the urine is reduced or prevented by just those agents which reduce protein catabolism. For instance, carbohydrates and alkaline salts both reduce protein catabolism and both reduce creatinuria; fats do not reduce protein catabolism and correspondingly do not reduce creatinuria. In regard to the cause for the difference in the behavior of men and women in the facility with which creatinuria is produced on ingestion of protein, the authors believe it possible that this may be related to the variations well known to obtain in the activity of the thyroid mechanism. In normal well nourished men, creatinuria has never been observed or experimentally produced. In women, however, creatinuria usually obtains. It is suggestive that periodic variations in thyroid activity occur with the menstrual period varying in degree with different women and that during pregnancy when the thyroid is also affected pronounced creatinuria has often been reported.

39. **Synthetic Capacity of Mammary Gland.**—The evidence presented in this paper makes it very probable that the mammary gland has not the capacity to synthesize the amino-acid, lysine. Further, the evidence submitted supports the view that as far as the proteins are concerned milk secretion, like growth, is ultimately dependent on the quality and quantity of amino-acids ingested with the food. The authors hold to the view that the amino-acid lysin is not dispensable for normal maintenance.

46. **Mineral Metabolism in Experimental Acidosis.**—The results of Goto's experiments indicate with a fair degree of decisiveness that next to the bicarbonates of the body fluids, the first major reserves of alkali drawn on in acid intoxication of rabbits are the alkali phosphates, particularly potassium phosphate, of the muscles, and the calcium carbonate of the bones. The bones do not lose calcium phosphate in appreciable amounts.

52. **Experimental Scurvy.**—The effect of meat and tricalcium phosphate on the development of scurvy was investigated by Pitz. He found that an improvement of the protein of the diet will protect guinea-pigs from scurvy for a number of weeks and will greatly prolong the life of the animals, even though the physical character of the diet has not been improved. But while laxatives and lactose will prevent the development of scurvy in guinea-pigs for twenty weeks, improvement in the protein of the diet, even when 10 per cent. of meat is added, will not protect them for more than thirteen weeks. When tricalcium phosphate was added with the meat the animals were protected for eighteen weeks. Sodium chlorid when added to the milk, rolled oats, meat, tricalcium phosphate ration, also effected some further protection, demonstrating that low chlorin is one among the many factors that may cause delay in the development of scurvy. This latter point is further emphasized by the remarkable protection afforded guinea-pigs against scurvy by the ingestion of calcium chlorid in the ration and shows that the calcium and chlorin ions are of greater importance in the development of this disease than is phosphorus. The physical character of the diet and the character of the flora of the digestive tract are clearly of prime importance in the production of this disease, but other factors, such as those which make the diet more nearly chemically complete, which stimulate appetite and increase the flow of digestive juices and increase the resistance of the animals, which decrease the permeability of the intestinal wall, and which aid in correcting a deranged chlorin metabolism, are of great importance and will protect the animals from scurvy for a considerable time. These experiments point to the little emphasized rôle of calcium salts in nutrition; namely, that of controlling the permeability of various animal tissues and thereby affording protection against invading agents.

59. **Virulence of Tubercle Bacilli in Sputum.**—The tubercle bacilli isolated by Petroff's method from the sputum of ninety cases of pulmonary tuberculosis in man, of which eight were incipient, twenty moderately advanced and sixty-two far advanced, were found to be of the human variety in eighty-eight of these cases. Of these eighty-eight cultures examined for virulence to guinea-pig (by subcutaneous injection), eighty-six proved to be virulent in amounts of 0.000,001 mg., ten of these were not examined below this amount and sixty-six produced tuberculosis (beyond the local glands) in guinea-pigs within two months in 0.000,000,01 mg. amounts. One of the two low virulent tubercle bacilli only produced a slight tuberculosis in guinea-pigs in 0.001 mg. amounts within two months, while the other produced no tuberculosis beyond the local involvement even in 1 mg. amounts.

No relation was observed by Corper between the virulence of the human tubercle bacilli for the guinea-pigs and rabbits, and the rapidity of the disease in man. No appreciable difference, within the limits of error of the experiments, between the virulence of human tubercle bacilli tested by subcutaneous injection for young (4 months) and mature (1 year) male guinea-pigs was noted on section forty-two and sixty-two days after infection. Corper found that human tubercle bacilli isolated on Petroff's medium do not appreciably alter their virulence for a period of from one to three months as tested in guinea-pigs, provided no detrimental influences are introduced. A second seeding on Petroff's medium within this time produces bacilli of equal virulence to guinea-pigs to the primary. Treatment of human tubercle bacilli with 3 per cent. sodium hydroxid solution for one hour at 37 C. does not appreciably affect the virulence of the bacilli for guinea-pigs while 6 per cent., sodium hydroxid for one hour at 37 C. will destroy the virulence of some cultures. The test for virulence of human tubercle bacilli isolated from the sputum of the same patient at different intervals (one and three months) give concordant results in guinea-pigs.

60. **Specific Fats in Immune Processes.**—The antigens dealt with by Warden were the specific fat antigens of the red blood cells of the sheep, the gonococcus, *Spirochaeta pallida*, the typhoid bacillus, and the cholera vibrio. He found that the fat complexes characteristic of certain bacteria and other cells replace the cells themselves in the production of specific antibodies in the blood of rabbits injected with them. The specificity of the antibodies obtained by the injection of cells probably depends in part or wholly on the configuration of the fats constituting the bulk of the cell surfaces.

61. **Coagulation of Blood and Anaphylactic Shock.**—Bulger is of the opinion that the changes in the coagulability of the blood during anaphylactic shock are due to changes in that stage of the coagulation process at which thrombin is formed through the interaction of prothrombin, calcium, thromboplastin and antithrombin (?). These changes are probably due to variations in thromboplastin. Antithmorbin changes are not great. In some animals there may be an increase in antithrombin which would aid in retarding the coagulation of the blood. There is no increase in antithrombin in rabbits. There was a marked increase in the rate of fibrinolysis after anaphylactic and peptone shock.

63. **Paratyphoid-Enteritidis Bacilli in Human Intestine.**—This paper deals with examinations of the feces of typhoid patients and convalescents and of patients suffering from other diseases. Nothing was found by Jordan and Irons that supports the assumption of a common or widespread distribution of paratyphoid bacilli apart from their association with specific disease conditions. Paratyphoid-like organisms are isolated more frequently from the stools of active typhoid cases than from those of healthy persons who had had typhoid some years previously. The intestinal flora of the latter in fact does not differ appreciably from that of normal individuals not known to have had typhoid. In a number of active typhoid cases different varieties of paratyphoid-like bacilli were found in the stools of one and the same individual. This corresponds with the generally heterogeneous bacteriologic characters of such stools. It is evident that the bacterial flora of typhoid stools is more varied than that of normal stools; however, the authors see no reason for assuming without further investigation that this condition is peculiar to the intestinal tract of typhoid patients. The observations made by Jordan and Irons on the stools of persons suffering from other disorders, especially disorders of the alimentary tract, indicate that the proportion of bacterial abnormalities in such cases is probably not very different from that in typhoid cases.

66. **Rat-Bite Fever.**—The chief points of interest in this case of rat-bite fever are the presence of a streptothrix in the polymorphonuclear leukocytes during life; in blood cultures after death; in smears of bone marrow, and possibly in the ganglion cells near the suprarenals. The streptothrix isolated in this case is more closely related culturally and morphologically to *Streptothrix putorii* than to *Streptothrix muris-ratti*. Morphologically, it differs from *Streptothrix putorii* in being shorter, as a rule. It differs culturally in producing a grayish color rather than a grayish-yellow color on glucose-blood agar, in growing less abundantly on plain and glucose agar, and in fermenting glucose, raffinose, maltose and leontose.

67. **Hemolytic Streptococci in Milk.**—Ninety-two samples of milk, forty-six pasteurized and forty-six certified, were examined by Davis. Hemolytic streptococci of the lacticus type were found in 23 samples. They were far more common in nonpasteurized than in pasteurized milk. They are less virulent for rabbits than the hemolytic streptococci of human origin. Two strains were found with moderate pathogenic power for rabbits. Davis points out that while, in general, one may practically be sure that organisms of the lacticus type are not dangerous to man, still individual organisms or strains of human, milk or bovine origin suspected of being responsible for sore throats or other infections in man should be studied carefully and compared with a view to finding specific common characters.

68. **Streptococci of Granules in Tonsils.**—Two types of streptococci, *S. hemolyticus* and *S. viridans*, were isolated by Pilot and Davis from the actinomyces-like granules of the tonsils. The viridans type showed strong anaerobic properties. The hemolytic cocci did not. Otherwise, the streptococci in their cultural and morphologic characteristics and pathogenic properties resemble streptococci from various parts of the mouth and from the crypts of normal and diseased tonsils.

70. **Immune Reactions in Measles and Rubella.**—Complement fixation tests were made by Tunnicliff and Brown with measles and rubella serum using, as a rule, a suspension of the diplococci isolated from the blood of measles patients, but also a mixture of strains, as the measles antigen, and a mixture of strains isolated from the blood and throat of rubella patients for the rubella antigen. The results indicate that the serum of measles and rubella patients contain complement fixing bodies for their respective diplococci to a slight degree early in the disease at about the same time the increase in opsonins occurs. Rabbits injected with various strains of measles and rubella diplococci develop agglutinins and opsonins. Agglutinins are demonstrable in the blood of immune measles rabbits often in high dilutions, both with homologous and heterologous measles strains. Satisfactory agglutination experiments are not possible, as a rule, until after long isolation of the diplococcus on account of spontaneous agglutination. Agglutinins are present in the serum of immune rubella rabbits, but generally only for the homologous strains. Specific opsonins are demonstrable in the blood of immune measles and rubella rabbits in high dilutions, and furnish the easiest and most reliable immunological method so far found, to differentiate measles and rubella diplococci from each other and from other nonhemolytic diplococci and streptococci.

72. Clinical Pathology of Mustard Gas Poisoning.—The blood and urinary changes in thirty soldiers gassed with mustard gas were studied by Hermann. These cases were of a very interesting variety, from the most severe types, those, which resulted fatally, to those showing only the slightest lesions, such as the most mild type of conjunctivitis. The mild cases of mustard gas burns of the skin show no changes in the blood or urine. Moderately severe and severe cases of mustard gas burns of the skin with some involvement of the upper respiratory tract after the first week showed definite changes in urine, blood urea and blood. The urinary changes consisted in a diminution of the urinary output, increased concentration and acidity, albuminuria, and diminished urea and chlorid output. In the sediment were found casts, renal epithelium, red blood cells and an increased number of leukocytes. Under forced fluids prompt improvement occurred. Coincident with these urinary changes the blood urea was high, but approached normal with the improvement in the urinary condition when fluids were forced. The blood showed a slight secondary anemia with a well-marked polymorphonuclear leukocytosis, a definite eosinophilia, and the appearance of myelocytes and young forms of leukocytes. The blood platelets were usually increased. No evidence of hemolysis was found. No leukopenia was noted at any time. The leukocytosis reached its height coincidently with the height of the secondary infection and fell with the improvement of the infection.

The temperature, pulse and respiration charts showed in the severe cases an initial period of shock. With the development of the necrosis and the secondary infection there was a corresponding febrile reaction. The bacteriologic examination of the infected skin lesions and furuncles showed constantly the presence of *Staphylococcus pyogenes-aureus*. In one bronchial cast obtained streptococci were present. Herrmann believes that the changes in the blood and urine may be interpreted as dependent on the secondary infection and, in part, possibly, to the absorption of toxic products from the necrotic skin, rather than to any direct toxic action of mustard gas.

74. B. Influenzae in Sinusitis and Meningitis.—Lacy advises to centrifuge the spinal fluid and culture it on various mediums, always using blood agar. In all cases of meningitis, either mild or severe, of indefinite etiology, the presence of gram-negative bacilli in direct smears or on cultures from cerebrospinal fluid or from the accessory sinuses of the respiratory tract should be looked on as probable *B. influenzae*. Lacy reports two cases of frontal sinusitis and two cases influenzal meningitis. In these four cases there were found two types of *B. influenzae*, one which retains its original short bacillary form, indefinitely on artificial mediums and the other which readily develops filamentous forms after a few days on moist blood agar.

89. "Endless-Chain" Blood Serum Treatment of Pneumonia.—Acting on the belief that persons convalescing from pneumonia have antibodies in their blood stream, Humbert bleeds the patient as soon as his condition permits, and bleeds as much and as frequently as possible. After the blood is collected it is allowed to stand at room temperature until the serum separates. It is then pipetted off and centrifuged. The clear serum obtained is now heated to 56 C. for thirty minutes. Tricresol, 0.3 per cent., is used as a preservative. This treated serum is placed in stock. When another patient comes in with pneumonia the type of pneumococcus is determined immediately and treatment is begun. When convalescence sets in, the above precedure is repeated. It is a case of one gives serum to two, two gives serum to three, and so on, the procedure becoming endless. The compatibility test is always performed. No attention is paid to syphilis in donors. Any living spirochetes that may be present in the blood stream are killed by the heating process. Tuberculosis is eliminated by frequent sputum and blood examinations after the crisis. The serum is administered intravenously, only once daily, unless the condition of the patient its critical. As high a dose as 170 c.c. has been administered without any untoward effects. Reactions occurred in only two of the eleven cases treated in each being of a mild character. There was one death—Type III.

92. Splenectomy Following Radium Treatment for Myelocytic Leukemia.—Twenty patients with myelocytic leukemia have been splenectomized at the Mayo Clinic. Eighteen patients were treated by means of radium exposures over the spleen prior to splenectomy. In each case the spleen was very much reduced in size and the general condition of the patient was very much improved as the result of radium treatment. The operative mortality for the entire group of twenty cases was one death, or 5 per cent. Nine patients have since died, from two months to one year and three months after operation. The total duration of history in eight of the nine fatal cases was from nine months to three years and six months. In seven of the eight it was more than two years. Seven patients were operated on early in the disease, that is, less than six months from the time of denfinite onset; six of these are alive, five are in excellent, or very good condition. In two cases of a chronic type the patients are alive ten months and one year and seven months, respectively, after splenectomy. In general, patients with the largest spleens at the time of operation have died first. Giffin infers that this probably indicates that these patients represented a more severe type of the disease. On the other hand, those with the smallest spleens at the time of operation have, in general, lived the longest.

A period of improvement in the patient's general condition followed operation in all cases save three. This general improvement consisted of a feeling of well-being, which may have been psychic, of an improvement in the appetite and the anemia, of a gain in weight, and a definite loss of the icteroid tint when it was present. Marked gain in weight was, however, almost a constant postoperative feature. The period of improvement was not of definite duration. The blood, after splenectomy, showed no definite alteration, with the exception of an increase in the relative percentages of both small and large "lymphocytes." A review of these cases reveals no evidence that the duration of the disease is altered in any definite way by splenectomy.

105. **Problem of Humidity Indoors.**—Lyon discusses this question of humidity indoors very thoroughly, especially as it affects the heating of homes. He says that if he were to put a heating system into a small house (in Minnesota) in the present state of development of hygiene and of heating engineering, he would choose a hot air furnace. He would have no outside air flue, but rather a cold return flue from every room to the base of the furnace. He would look to this system to secure circulation, which is now recognized as a very important hygienic factor. He would trust to leakage for renewal. He would have double windows, expecting even with these to have ample oxygen for an ordinary family. He would supply moisture by a sufficient number of broad shallow pans just above the fire pot, the water level in these being automatically maintained by connection with the city water system. He would have a good psychrometer and see to it that the relative humidity was kept about 40 per cent. He would have a good thermometer and keep the temperature at 65 F., or not above 68 F., and, he would expect good health and comfort dividends on the outlay of money and trouble required to get these conditions.

107. **Surgical Treatment of Progressive Ulnar Paralysis.**—Adson reports three cases of operation on the ulnar nerve. The nerve was very much enlarged and presented one or more so-called "neuromas" (intraneural fibrous tissue). The enlargement was of the fusiform type with definite thickening and hardening of the nerve itself and the neuromas were quite definitely circumscribed, though more or less diffuse throughout the nerve tissue. The ulnar groove between the internal condyle and olecranon was very shallow, owing, in two cases which were end results of old fractures, to an overgrowth of bone from the olecranon. In one instance a very definite bony spur of the ulna was present, without a history of fracture. It appears that the diffuse thickening of the nerve is due to frequent or constant but very slight trauma, such as bruising, or to the stretching of the nerve over some of the bony prominences. Small hemorrhages in the perineurium and in the endoneurium result, causing inflammatory reactions and the deposit of scar tissue. As the scar tissue tends to contract, many of the fibers become strangulated and eventually are destroyed, resulting in a gradual and progressive atrophy of the ulnar nerve. The condition is characterized by: (a) sensory changes—paresthesias and anesthesias; and (b) atrophy of the muscles involved, with gradual increase of motor paralysis. The surgical treatment consists of transference and fixation of the nerve to a position internal to the inner condyle, with longitudinal splitting of the epineurium and perineurium, or the resection of neuromas followed by anastomosis.

114. **Plaster Splint Treatment for Compound Fracture of Long Bones.**—The method of procedure advocated by Miller is as follows: The wound in the limb is dressed, and the entire limb is bandaged with one thickness of flannel bandage. The limb is measured for the desired length of the splint, then a piece of flannel or muslin bandage, the required length, is moistened and stretched out on a smooth long table. Starting at one end of the piece of flannel, plaster bandages soaked in warm water are laid down on this flannel (or muslin) from left to right, and back from right to left until the entire bandage has been used, and another is now used, if necessary, until the desired thickness is obtained. The plaster splint is now made; it is soft and pliable and is put on the limb lengthwise, the limb being held in position. The splint is bandaged onto the limb by means of gauze bandage, being molded at same time. The second splint is now made and applied in the same manner. The limb is held in position by means of sand bags until the splints are dry, usually about fifteen minutes. For forearm, three such bandages are usually sufficient for both splints, made long enough to immobilize elbow, and going down well onto hand. About seven are necessary for the splints in cases of fracture of the tibia and fibula, immobilizing both knee and ankle.

131. **Fascial Transplants in Repairing Hernia.**—Singleton has used transplants from the fascia lata in twelve cases of inguinal and one case of postoperative ventral hernia. These were extremely severe hernias, having very large rings, with a deficient amount of muscle and material for buttressing, and in which successful repair by any of the usual methods was doubtful. Four of these cases were recurrent hernias; two were complicated by the intestine sliding into the sac. The other cases presented either the direct type or the type of very large rings with a deficiency of the conjoined tendon. In the case of the very large postoperative ventral hernia the muscles could not be brought together and the fascia was successfully transplanted with a perfect result in the way of repairing the defect. Singleton is firmly of the opinion that this is an advantageous procedure and that it should be used

more frequently in certain cases of *inguinal* abdominal hernia and especially where it is found necessary to use foreign materials, such as the filigree wire to repair defects in the abdominal wall.

1. **Epidemic of "Central Neuritis.**—Scott analyzes a certain epidemic which broke out in the earlier months of 1917 among the laborers on a sugar estate in Jamaica. The onset in each case was sudden, the patients being attacked while at work and apparently in good health. The initial symptoms in all cases were conjunctivitis and stomatitis. Thereafter the patients could readily be divided into two categories: (1) with intestinal symptoms; (2) with nervous symptoms. The diet of those affected consisted exclusively, or almost exclusively, of sugar cane. The cane tops, which are cut or broken off, are covered with small hairs which are very irritating and may have set up the original conjunctivitis and stomatitis, and, when swallowed, the subsequent diarrhea. Fresh cases ceased with the cessation of the crop or almost immediately after.

No case with early diarrhea exhibited any affection of the nervous system. In nervous system cases the patients were always constipated until the final two or three days before death. Wassermann reactions with both the blood serum and the cerebrospinal fluid were invariably negative. Blood examinations revealed very little abnormality as regards total counts; differential leukocyte counts showed in all cases a marked relative lymphocytosis. Arneth index was very different from what is found normally in natives in the tropics.

The morbid anatomy of the nervous cases is typical of a "central neuritis." Scott sees no reason for thinking that the disease is pellagral in nature, or that it has any relation to pellagra. There is no reason for regarding it as beriberi. There are many contraindications to the condition being a new form of "deficiency disease." There is every reason for considering these cases as representing the acute form, or acute stage, of what has for many years been erroneously spoken of as "peripheral neuritis" in Jamaica. There is no positive evidence that the disease is microbial in origin, at least not a bacteriemia. All the signs and symptoms tend to its being a condition of "intoxication."

2. **Treatment of Malaria.**—Forty-nine men received quinin bihydrochlorid by intramuscular injection, 15 grains, simultaneously into each deltoid, with 10 grains, orally, or hydrochlorid thrice daily, totaling 60 grains daily, for 12 days. Of these 5 relapsed (10 per cent.). Relapses occurred in an average of 34 days (extremes sixteen to seventy-two days). This is known officially as the Aldershot C 17 treatment. Many of these men had been given daily doses of quinin (generally only 5 grains) after they had been discharged from the special malaria wards. The authors suggest that the low proportion of relapses may partly be due to this continued medication. A second series of thirty cases were subjected to the treatment. In twenty-six a parasitic relapse occurred in eight to fifty-six days, average eighteen days. In four cases there was no parasitic relapse within an observation period of sixty-seven to 100 days.

The authors believe that the season at which treatment for malaria is given influences the results obtained. The same treatment if carried out on different occasions may give quite dissimilar results. Broadly speaking, a very small percentage of cures is obtained in the winter and spring and a comparatively high percentage in the summer and autumn.

3. **Id.: Intravenous Injections of Neo-Arsphenamin.**—The authors found that single intravenous injections of neo-arsphenamin in doses of from 0.45 to 0.9 gm. control the febrile paroxysms and cause the disappearance of parasites from the cutaneous blood, as a rule within one day, in simple tertian malaria. Parasitic relapses occur, on an average, in twenty-one days. The curative effect of a single inpection of the drug in the doses used is practically nil.

4. **Quinotoxin Treatment of Malaria.**—A dose corresponding to 5 grains of quinotoxin hydrochlorid was given orally to five patients and 10 grains to four patients on each of two consecutive days. The drug had practically no action on the parasites or the fever, and so is inferior in its action to similar doses of quinin sulphate in simple tertian malaria.

5. **Estimating Quinin in Animal Tissues.**—Delicate methods are described by the authors for the estimation and detection of quinin in animal tissues and liquids. They found that quinin does not normally suffer change in putrifying urine or feces and that quinin introduced into an animal in large doses accumulates in most of the tissues at very much higher concentrations than in the blood. Of the quinin present in the blood, more than three fourths is in the serum (plasma?). Normal red corpuscles take up very little quinin. After intraperitoneal injections the suprarenal glands take up quinin at much higher concentration than any other tissue examined; the kidneys probably come next in the series. The healthy human kidney excretes quinin at much higher concentration than that at which it is present in the contemporaneous blood. During an attack of blackwater fever it appears to lose this power. The liver of rabbits, guinea-pigs and oxen rapidly attacks quinin postmortem and presumably during life. The properties of the active agent suggest that it is an enzyme. The product or products presumably represent normal metabolites of quinin in the living body.

Experiments directed to ascertain whether quinotoxin is a normal metabolite have shown that (*a*) it is attacked by liver extracts; (*b*) when ingested by mouth it produces alimentary disturbances, but some is absorbed and some at least is excreted unchanged in urine; (*c*) any antimalarial action which it may exert is so slight in comparison with that of quinin as to be negligible. A given dose of quinin gives rise in different men to very different amounts of quinin in the blood. The excretion period of quinin by the urine differs greatly in different men—ranging from forty-one hours (after a single dose by mouth) to seven and a half days (after the last of a succession of large doses). About 90 per cent. of the quinin injected intravenously disappears from the blood within one minute. There is a striking association between symptoms of quinin intoxication and high concentrations of quinin in the blood. When quinin is administered in a succession of large doses, an abnormally large proportion (from 90 to 93 per cent. of that ingested) is metabolized. Quinin may fail to effect a radical cure of malaria even when it has reached, and maintained for some time, a concentration in the blood so high as to be barely tolerable to the patient.

10. **Curse of Immobilization.**—Dowden is of the opinion that thousands of soldiers have been more or less disabled for life simply and solely on account of prolonged immobilization of injured limbs. He emphasizes the following four points: Nature is the most wonderful surgeon, especially when encouraged; septic wounds should be thoroughly drained; from the very beginning frequent passive and active movements should be carried out, steadily increasing the range; splints should never be used except when absolutely necessary, and then only for as short a time as possible, and should never interfere with passive and active movements. Massage time, a concentration in the blood so high as to be barely is a most excellent adjunct—the best—to active movement. Dowden lays little stress on the value of electricity or baths. When passive or active movements are begun early, pain is the danger signal that shows harm is being done, and the movements should be modified temporarily. When after prolonged immobilization adhesions have formed, however, pain has to be endured while the adhesions are being stretched or broken. Injuries to joints, even though septic, are not a bar to movement; the joints should be moved gently and encouraged, short of pain. For the last twelve years, Dowden has treated all fractures of the scapula, clavicle, humerus, and many of the forearm, without splints. Every movement of all joints and muscles is encouraged, first of all passively and as soon as possible actively, and this should be carried out frequently during the day. By the time the fracture has consolidated, all the movements of the joints are perfect, provided the damage has not been too great.

12. **Blood Pressure in Pulmonary Tuberculosis.**—Nineteen patients were examined by Cyriax as to blood pressure. The pressure in the two arms is by no means invariably the same. Five patients, all males, were confined to bed, except where otherwise stated. Tubercle bacilli have been found in all their sputa. In two cases differences of more than 5 mm. in the systolic pressures were not found; two observations were made on each patient at intervals of some days. Both had lesions in both lungs. In the remaining fourteen cases, not confined to bed, differences in the systolic pressure of more than 5 mm. were found in six. All six are cases of bilateral disease; tubercle bacilli have been found in the sputum. The differences amounted, in the male patients, to 7, 8 and 13 mm., respectively; in the female patients to 14, 8 and 10 mm. The systolic pressure in the arm appears to be lower, as a general rule, on the diseased side in a unilateral, on the most diseased or most active side in a bilateral lesion. Further investigations are in progress.

21. **Malignant Disease of Upper Extremity.**—One of the cases cited by Grant, one in which several limited operations had been performed for an epithelioma of the hand, where ultimately the disease had extensively involved the axillary glands and lymphatic vessels, demonstrates the advantages which Berger's operation gives in sweeping away, without a difficult, tedious, and possibly incomplete dissection of the axilla, all possibly infected tissues. The second case was one of very extensive carcinomatous ulcer arising in the scar of a large burn involving the greater part of the skin of the right upper arm. The third case was one of a round-cell sarcoma of the scapula.

27. **Decortication of Lung.**—Delorme coined this term some years ago to express the releasing of the lung by peeling off the thick, stiff shell of false membranes crowding on it. It has proved particularly useful for the sequels of war wounds of the chest, especially when the decortication is done without further delay as soon as the lung is found incapable of returning to contact with the wall even after a course of respiratory exercises. In forty-nine cases of chronic empyema from a war wound, compiled from the experience of four British and French surgeons, there was no fatality for which the decortication could be incriminated, and the results were reported as highly gratifying. The decortication was an extremely mild and simple procedure when the empyema was "cold" and the general condition good. The decortication promises equal success with chronic pleurisy consecutive to influenza. Radioscopy readily shows the encapsulating shell.

28. **Lethargic Encephalitis.**—Marinesco reports the pathologic histologic findings in lethargic encephalitis as an inflammatory polioencephalitis, and suggests treatment by injecting convalescents' serum into the arachnoid cavity.

30. **The Eye Symptoms with Skull Wounds.**—Terrien calls attention to the diagnostic importance of three symptoms which reveal hypertension and which may give the clue to the trouble in certain cases. The triad includes diplopia, restriction of the visual field, and choked disk. They subside after lumbar puncture as the hypertension is relieved, but if this is not done, irreparable damage may result. They explain the transient visual disturbances sometimes observed long after trephining, and they may reveal some brain lesion which had previously escaped detection. The symptoms seem to occur more frequently when the trephining opening was small, and they emphasize the necessity for caution in closing gaps in the skull with metal plates or cartilage.

32. **Appendicitis Simulating Pulmonary Tuberculosis.**—Schoull reports some cases in which râles, congestion in the apexes, and other symptoms of pulmonary tuberculosis fluctuated with exacerbations of chronic appendicitis, and disappeared completely after appendicectomy. The pathologic condition of the appendix was discovered accidentally at an ovarian operation in one case. In three of the cases, consultants did not accept his diagnosis until two of the apparently doomed patients regained their health after the appendicectomy. The third still rejects an operation. Schoull regards the pulmonary disturbances as a *kind of metastatic congestion.* Fever not over 38 C. keeping up for several months or years points to some other cause than pulmonary tuberculosis. It suggests appendicitis *in adults and also in children* if adenoiditis can be excluded. An "abdominal past" is also instructive.

34. **Hypochlorite Treatment of Ulceromembranous Angina.**—Lagarde states that neutral solution of chlorinated soda promptly cured twelve rebellious cases of Vincent's angina. *After the mouth* had been rinsed twice and the throat gargled several times the first day, the relief and improvement were pronounced, and no further spirilla or spindle-shaped bacilli could be discovered by the end of the second day. Dakin's solution in these cases exerts an unmistakable detersive, bactericidal and phagocytic action, so that the general health rapidly recuperates.

36. **Influenza.**—Lereboullet summarizes the present status of our knowledge on influenza and reiterates that the predisposition for other infections which influenza entails renders individual isolation exceptionally *important.*

37. **Azotemia in Influenza.**—The azotemia is of moderate degree but it is remarkably frequent, even in the young on a fluid diet.

38. **Influenza.**—Rénon and Mignot remark *in this review* of the present status of influenza that it has benefited much by the progress in hygiene realized since 1890. In five days *recently*, Bar had 19 develop influenza out of 79 inmates of the Tarnier maternity as also 14 of the 54 nurses and 4 of the infants. Then masks of three or four layers of gauze were *worn by* all and no further cases developed.

38. **Treatment of Influenza.**—Ravaut remarks that the symptoms on the part of the lungs are comparatively mild in the hypertoxic *form of influenza, and a fixation* abscess, tonics for the heart, and epinephrin seem to be indicated, with possibly hexamethylenamin. In one case antipneumococcus serum on four successive days seemed to be unmistakably responsible for the recovery. In other cases the benefit was less apparent. In the cases with edema of the lung, the interference with the local circulation calls for abundant and repeated bloodletting, and nothing must be given to increase the blood pressure, as long as the circulation in the lungs is blocked by the hemorrhagic-serous *fluid. Perhaps one reason why the young* and vigorous become asphyxiated quicker is because their heart keeps working so forcibly. Withdrawal of 500 or 700 gm. of blood may relieve at once, and the earlier this is done the better. Every minute's delay sees more blood oozing into the interstices of the lung tissue, and the circulation grows more and more difficult. The lungs were found gorged *with* coagulated blood in one case in which venesection had been deferred too long, and blood poured from the chest even after death. Many patients were undoubtedly saved by withdrawal of 500 gm. of blood on four successive days. Prompt venesection certainly warded off acute pulmonary edema *in many* cases. The main point *is to apply* it in time *and* without hesitation. When there was albuminuria, hexamethylenamin was found a useful adjuvant. Comparison of the blood of patients treated with and without venesection showed that the resulting anemia was no more intense than in the disease left to its own course. It is not dangerous, while it is the one chance of salvation when it is really needed. An intravenous injection of from 2 to 6 c.c. of a solution of 1 gm. iodin and 2 gm. potassium iodid in 100 gm. of water was given to many of the patients, and in his 1,000 injections of the fluid he never saw any signs of intolerance or injurious action in any way. The temperature often dropped afterward but rose again later to drop anew at the injection the next day. In three exceptionally severe cases the recovery seemed to be due to these injections alone. Some of the patients with *pulmonary complications* were given ten or twelve of these injections, and sometimes with highly appreciable results.

40. **Treatment of Influenza.**—Lereboullet reiterates that the first and main thing is individual isolation of the patient. Even in a mild case, he should stay in bed from the very first and eat little, *only fluid food* if there is much fever, but drink copiously of water and lightly alcoholized drinks. Meat, eggs and bread should not be given until two or three days after complete apyrexia. *He warns against the* abuse of purges at the start. In grave forms, with very low blood pressure, epinephrin may be useful. He gives 10 or 15 drops by the mouth two or three *times. Given* by subcutaneous injection, it is liable to cause severe disturbance in these cases. The heart may have to be reenforced with camphorated oil, or strychnin or both. Caffein is liable *to bring on delirium.* Wet packs of the chest, at 25 C., changed three or four times a day, have rendered good service. With a tendency to pulmonary edema, venesection *must* be *abundant* and repeated, otherwise wet cupping may suffice. His experience *with* serotherapy was limited, but the results were promising. Drugs that have a depressant action should be carefully avoided, including purgatives, but he advocates *moderate* doses of *quinin,* for its tonic action, 0.25 gm. for example, morning and evening.

41. **Is Influenza a Spirochetosis?**—In eight of twelve influenza cases examined, spirochetes were cultivated from the urine. The spirochete resembled that described *in an official* circular in 1917 as not inducing hemorrhagic jaundice and not pathogenic for guinea-pigs.

42. **Physiologic Solutions by the Vein After Hemorrhage.**—Animals more or less exsanguinated were given *intravenous* injections of different "artificial serums," in the research described. The most effectual was a solution of 7 per thousand sodium chlorid plus 5 per thousand lactose or glucose. With this it was possible to keep alive a dog that had been repeatedly bled until he had no more than 21 per cent. of his red corpuscles, and even *continue the hemorrhages* until he had only 5 or even 3 per cent. of his reds. Addition of gum acacia did not seem to offer any advantages over this salt-sugar serum. In large *proportions,* the gum acacia exerted a toxic action, as also sodium bicarbonate in any strength for these hemorrhage animals. The artificial serums were unable to ensure durable survival of the much exsanguinated animal, but direct transfusion of citrated blood permitted this. Complete restoration was the rule, showing that the nerve centers had not suffered from the loss of blood. The practical conclusion is that in case of severe hemorrhage, infusion of the salt-sugar solution will restore the *mass of* the circulating fluid and tide the exsanguinated along until he can be given a transfusion of blood. Only this latter will save in desperate cases.

44. **Sterilization of Wounds by Electro-Ionization.**—Parin relates that a single application of electric ionization with zinc sulphate promises to completely sterilize a war wound. His experience, he says, has been satisfactory in the fifteen cases in which he applied this method. In two of the cases streptococci were unusually numerous and the *sterilization* was not *complete;* possibly some other metal might be more destructive than zinc for the streptococcus. Friel is the only one that has applied this ionization method in sterilization, so far as Parin knows. Friel reported in 1917 his success with it in treatment of suppuration in the middle ear and the

maxillary and frontal sinuses, and since then has been using it for war wounds.

45. **Pain of Sympathetic Origin.**—Girou means by this, pain in the sympathetic nervous system in distinction to pain for which peripheral nerves are responsible. Lesions of the latter are manifested by paralysis, impotence and pains; lesions in the sympathetic system are manifested by contracture, circulatory and trophic disturbances and pains, but the pain is not so intense as in the other group. He has operated in many cases of causalgia and contracture and has found this distinction constant and pronounced. With causalgia of the Weir Mitchell type the median or popliteal nerve was always found injured, never the sympathetic nerve. The nerve seemed pathologic over a stretch of up to 10 cm. and the D. R. was generally complete. The lesion was too extensive for any direct intervention, and all that could be done was to arrest the conduction of the pain to the centers of consciousness. Sicard accomplishes this by blocking the nerve with intraneural injection of alcohol at 60 degrees. Girou obtained the same result by ligating the nerve with No. 2 catgut, drawn moderately tight. The ligature has to be made at a point on the median nerve above the sympathetic fibers reaching it from the sheath of the humeral. Ligation lower down would irritate these fibers and induce contracture. The ligature induces violent pain for an hour unless a little morphin is injected at the close of the operation. He has been treating causalgia in this way for three years. With flexion contracture of the hand, he invariably found the periarterial sympathetic sheath injured, showing the effect of some surgical ligature, or being bound down by cicatricial tissue. This hampers the circulation in addition to the direct injury of the sympathetic nerve fibers. These are the cases that benefit by cutting off the network of sympathetic fibers ensheathing the artery, that is, Leriche's method of periarterial sympathectomy. The two kinds of pain may be associated, causalgia and the sympathetic irritation pain, so that both the median nerve (the one usually involved) and the sympathetic may require treatment. In conclusion he warns that in ligating an artery, the sheath should not be ligated with it. Those who, like himself, have witnessed contracture develop after ligating the humeral artery, will appreciate the necessity for this precaution.

46. **Action of Autolysates.**—This is the opening lecture of the course on experimental and comparative pathology. Personal experimental research is described which shows, among other things, that the products generated in cells that have lost their vitality may have a pronounced effect on certain body functions. For example, with cirrhosis of the liver the cells die off, that is, they undergo autolysis, and the autolysates resulting pass into the circulation and by their toxic action check production of urine. On the other hand, with cirrhosis of the kidney or interstitial nephritis, the diuresis is increased, for the autolysates from kidney tissue do not have the property of reducing the secretion of urine but rather tend to increase it. The edema of the legs with the ascites of cirrhosis of the liver is explained by the insufficiency of the kidneys resulting from the toxic action of the liver autolysates. The edema may precede the ascites and is not a consequence of it. Further research is necessary on the effect of autolysates from partially devitalized organs left in the body. The kidney is the organ best adapted for such experimental work. For instance, if the vascular pedicle of the kidney is ligated and the circulation interrupted for seven or eight hours and then restored, a rise in blood pressure follows and the cardiac systole is reenforced. This experiment reproduces what must occur in the course of pathologic autolysis, and explains the mechanism of the two most important manifestations of interstitial nephritis, namely, the hypertension and the hypersystole.

Progrès Médical, Paris

51 Foreign Bodies in Esophagus. Bichaton and R. Rendu.—p. 361.
52 *Mania from Otitis; Recovery. H. Damaye.—p. 362.

49. **Plastic Motor Surgery.**—Bernard is enthusiastic over the promise of what he calls *orthopédie cinéplastique*. Although the experiences are not very numerous, the results speak so eloquently, he declares, that this method of plastic motor surgery ranks among the greatest discoveries of orthopedic surgery. It should be accepted with entire confidence and be applied on a large scale in order to restore the functional use of limbs to the maimed. From the physiologic point of view, the plastic motors are capable of doing at the same time the same kind and the sum total of the work of the masses of muscles which they replace. The amount accomplished does not reach its maximum unless the prosthesis is perfectly adapted to the shape and force of the plastic motor. To realize this vitalization of the prosthesis, the surgeon and the mechanical orthopedist must work together in order to solve in a satisfactory manner this difficult problem of such immense social interest. Bernard reviews the literature and gives illustrations of different technics, but does not speak of any personal experience with the method.

52. **Mania with Otitis.**—Damaye's patient was a military telephone operator and he suddenly developed subacute mania in the course of a staphylococcus double otitis media. Both persisted for nearly two months when they gradually subsided and by the end of the month normal conditions were restored. The mania was the first symptom that called attention to the otitis. A mastoid operation became necessary, and after this gradual recovery followed under a silver salt, raw meat, cacodylate and iodin. The mania was of the stereotype form with confusion.

53 *Immune Substances in Treatment of Tuberculosis. H. Wassitsch and C. Spengler.—p. 1489.
54 The Deycke-Much Partial Antigens. F. Oeri.—p. 1498.
55 *Neo-Arsphenamin in Treatment of Anthrax. J. L. Gsell.—p. 1505.

53. **Immune Substances in Treatment of Tuberculosis.**—This communication from Spengler's Institute at Davos reports the application of his I K method of treatment in 484 cases. The results are said to surpass those obtained by any other treatment and in a shorter time. The bacilli disappeared from the sputum in twice the proportion realized in similar groups in other sanitariums at Davos.

55. **Neo-Arsphenamin in Anthrax.**—The case reported can be classed with those published by Becker, Bettman and others in which intravenous injection of neo-arsphenamin arrested severe anthrax. A total of 0.75 gm. was injected in two days, and improvement was evident at once.

57 Foreign Body in Esophagus Perforates Mediastinal Artery. G. Massa.—p. 305.
58 Putrid Infection of Wounds. L. Fioravanti.—p. 313. To be cont'd.

56. **Albee's Operation for Pott's Disease.**—Maragliano's impressions are decidedly favorable for this operation, provided too much is not expected of it. He gives the details of his thirty-four cases, and says that the poverty of the families explains the small percentage of durable successes. There should be five or six months of horizontal reclining, and the corset should be worn for at least another six months. These conditions could not be realized in all his cases.

69 Induced Pneumothorax for Wounds and Effusions in Chest. E. Aievoli.—p. 859.
70 Biology of the Pneumococcus. A. Ferrannini.—p. 862.

60. **Color Reaction in Typhoid Urine.**—De Silvestri calls attention anew to this very early and constant reaction in typhoid urine, and gives some cases in which the findings of this test were all that testified against typhoid until the course of the cases confirmed its evidence. He discovered the reaction in studying the phenols in the urine, and several years' experience has confirmed its reliability. He would like to have those who apply this test inform him of their experiences with it. His address is E. de Silvestri, Via Principe Amedeo 29, Turin, Italy. The test is the color reaction when 3 c.c. of filtered urine is cautiously added from a pipet to a mixture of 2 c.c. of ferric chlorid and 4 or 5 drops of pure sulphuric acid. At the zone of contact between the reagent and the urine, a brownish yellow tint appears and spreads upward. A ring of turbidity, with greenish reflections, forms on the surface of the urine, but this disappears on agitating the test tube. The brownish yellow, or chestnut tint, however, shows no change on agitating or heating the fluid. The reaction occurs without heating. If there is precipitation of urates and albumin, it is better to repeat the test with urine freed from them. This reaction is positive in the first days of typhoid and paratyphoid B and, although less pronounced, in paratyphoid A.

64. **Shrapnel Ball Free in Right Ventricle.**—The projectile had entered tangentially to the iliac crest and lodged in the wall of a large vein. It dropped in time into the lumen of the vein. Symptoms on the part of the heart marked its passage through the right auricle, but after it reached the ventricle it has apparently caused no further disturbances during the year to date.

65. **The Febrile Pandemic.**—Minerbi emphasizes certain points in which the present epidemic in its incidence at Ferrara seems to differ from influenza, especially the sparing of the well-to-do; the fact that the congestion in the nose and accessory cavities is brief and fleeting; the pneumonia is lobular, instead of lobar, while the glands in the neck and carotid sulcus are not palpable, contrary to what occurs from the first in influenza. Those who abstain from salicylates and other drugs seem to get along better.

67. **Tests for Changes in Motor Functions.**—Besta is professor of nervous and mental diseases at the University of Messina, and he here describes a series of tests which reveal impairment of the sense of direction, like Bárány's finger-touching test. He shows that a lesion in the parietal lobe may give findings simulating those with a cerebellar lesion under certain conditions. He has worked out a number of other tests, besides Bárány's, in which various groups of muscles are called on, as he describes in detail with their interpretation, movements of the neck, trunk, and limbs. The value of these tests in neurologic examination after skull wounds is emphasized. They constitute, he says, "unless I am mistaken, a completely new chapter of the physiopathology of the cerebral cortex." For example, if the arms are raised vertically and, with the eyes bandaged, the trunk is twisted around and then back to place, the trunk is left at more or less of an angle to its primal position in certain pathologic conditions. The legs behave differently in this test on the sound and affected side. Walking along a straight line, back and forth, for 30 or 40 feet and then continuing with eyes bandaged reveals in pronounced form the tendency to deviate to right or left.

68. **The Febrile Pandemic.**—In these further contributions to the referendum, Pane, Liverato, Sclavo and Ascoli contribute their experiences. The latter remarks that certain circumstances suggest the possibility of an immunity and hence of specific vaccination. Copious drinking of fluids and sugar solution by proctoclysis were his main reliance. In the plethoric and the asphyxiated, he drew 500 c.c. of blood. He also speaks rather favorably of addition of a silver salt to the proctoclysis fluid. In addition to the Italian referendum running through several numbers, a full review is given in each number of publications on the subject in other countries, but the *Riforma* does not commit itself to a diagnosis, merely calling it the febrile pandemic. The medical senators, Cardarelli, Bozzolo, Micheli and Senise describe their experiences as chiefs of medical clinics. Bozzolo uses a mask that is held with wire far enough from the mouth to keep it from getting moistened. Against the pneumococci in the mouth, he advises a weak solution of ethyl-hydrocuprein (optochin) with a little thymol. Antipneumococcus and antistreptococcus serum have been used to advantage, as also convalescent's serum, but he has formed no definite judgment as yet. The young are mainly affected in his district (Turin). Micheli's impressions are favorable as to the benefit from early injection of antistreptococcus serum. Possibly it serves only as a heteroprotein therapy.

Rivista Critica di Clinica Medica, Florence

71 *Jacksonian Epilepsy. F. Schupfer.—p. 445. Concluded in No. 39, p. 457.
72 Tonus and Hyperexcitability of Vagus-Sympathetic System. L. Siciliano.—p. 448.

71. **Jacksonian Epilepsy.**—Schupfer's patient is a boy of 14 who has been having jacksonian epilepsy for two or three years, the focus being probably at the foot of the second right frontal convolution. Analysis of the features of the case suggests a gliomatous tumor in this region although trephining in the rolandic region brought such relief that there have been no symptoms since. The diagnosis was sustained by the negative findings in the rolandic region.

73 The Hypotheses of Energy. (Bioenergética y termoquímica alimenticia.) R. y Abaytúa.—p. 433.
74 *Partial Colectomy. L. Urrutia.—p. 451.

74. **Partial Colectomy.**—It is almost impossible to differentiate between a tuberculous and a malignant process in the colon, but this is immaterial, Urrutia remarks, as partial colectomy is required for both, unless the lungs or small intestine are too much involved. The zone of lymphatics has to be thoroughly removed in either case. An inoperable tuberculous process may improve to such an extent under exclusion and heliotherapy that in a few months the process can be resected, or it may heal completely. In one of his cases all the disturbances vanished completely in a few months after unilateral exclusion with ileotransversostomy, and the large tumor could be no longer palpated. The lymph glands below as well as those above should be removed with a carcinoma of the cecum or appendix, and he advises the same even with a purely tuberculous process, as exact differentiation is so difficult and there is always danger of secondary malignant degeneration. He makes a point of extensive resection even although in some of his cases excellent functional results were obtained with economical resection. Side-to-side anastomosis with the Murphy button, by Pauchet's aseptic technic, is by far the preferable technic, he declares. The whole operation can be done without changing gloves. He knows of two cases with no signs of recurrence eleven and seventeen years after a radical operation for cancer of the cecum. The arrangement of lymphatics of the colon, in comparison to those of the small intestine, explains why malignant disease of the colon is so much less liable to spreading and metastasis than with cancer of the small intestine.

75 *Adenitis of Dental Origin. Landete.—p. 449.
76 Albumin Milk in Infant. Feeding. A. R. Lozano.—p. 472.

75. **Adenitis of Dental Origin.**—Landete is professor in the dental school. He gives an illustrated description of the relations between the glands in the face and neck and the teeth, tracing the development of infectious processes in connection with different teeth, especially in children. The differential diagnosis is discussed, and the advantages of vaccine therapy are extolled when the adenitis is once established. If the effect of the vaccine in a few hours is slight or transient, this warns of the presence of pus which must be cleared out of the way before the vaccine can exert its

efficacy. The focus must be drained continuously. He prefers for this a loop of fine copper wire, such as is used for electric light, the outer ends turned back, and the whole held in place with a strip of gauze. This little loop can be inserted and removed without inconvenience through a minute incision. He prescribes flushing with an antiseptic unless the cavity is so large that the Carrel method can be applied. Even when the adenitis is only indirectly connected with the mouth, the vaccine made from the mouth germs still manifests its efficacy. Although if the streptococcus or other germ is positively recognized, its specific vaccine can be used. Otherwise the mouth vaccine should be given the preference, and he reports striking success with this even with severe furuncles, anthrax, etc., quite far from the mouth. On the other hand, he has sometimes obtained good results with other vaccines, the staphylococcus for example, in buccal and perimaxillar infections. The vaccine he uses is made by the municipal laboratory from a mixture of various specimens of streptococci and a gram-negative diplococcus isolated from the roots of teeth recently extracted, from pus from osteomyelitis of the jaws, from the exudate of a pathologic eruption of the teeth, etc. These bacteria are found constantly in healthy mouths and in polymicrobian buccal infection. They can be readily cultivated in fresh and unaltered human blood or the usual culture mediums. The vaccine contains 250 millions per cubic centimeter, killed by chloroform and heating to 55 C. for half an hour. The sterility is tested by aerobic and anaerobic cultures, and by subcutaneous injection of 2 c.c. of the vaccine in a guinea-pig, weighing 300 gm., without appreciable local or general reaction. Wounds of the mouth, complications of carious teeth, adenitis, osteomyelitis, etc., all benefit both in prophylaxis and in treatment. For the latter he injects 0.5, 1, 1.5 and 2 c.c. in turn with intervals of from two to five days. In prophylaxis, he injects 0.5 c.c., doubling this dose after two days. For children of 5 to 10 he uses a half of the adult dose, and from 3 to 5 a quarter. The doses should also be reduced for patients with heart or kidney disease or suspected of tuberculosis. There may be a general, local or focal reaction, and these should be supervised to avoid the focal reaction, in particular. The vaccine kept in a cool dark place has shown no appreciable alteration over periods of more than a year.

82 Treatment of Lumbricosis in Children. L. Gonzaga.—p. 310.

79. **Colloidal Gold Reaction in Diagnosis of Syphilis of Nervous System.**—Madeira's experiences with this test early in involvement of the nervous system have been extremely favorable. He has been a pioneer with it in Brazil.

81. **Dangers and Fallibility of Exploratory Puncture of the Liver.**—Clark reports a case in which the minute injury from the tip of the needle entailed fatal hemorrhage, although necropsy demonstrated that no large vessel had been injured. In two cases the puncture gave positive findings, but the diagnosis had been certain before and the operation followed at once. In another series the exploratory puncture had failed to reveal the pus pocket discovered at necropsy. In one young man three punctures had been made, in different interspaces, all negative, but that side of the chest contained 6 liters of chocolate pus with total atrophy of the lung. In another case with various negative punctures, the pus had accumulated in the peritoneum, and was encapsulated by false membranes. In another case necropsy revealed the liver studded with a hundred small abscesses, but puncture repeated at several points had not happened to hit one.

86 *Can Trachoma Be Cured? J. Santos Fernandez.—p. 343.
87 Ileus and Its Treatment. E. Yaniz.—p. 349.

86. **Can Trachoma Be Cured?**—Santos Fernandez remarks that in his many years of practice few have been the cases of actual trachoma which he has seen completely cured. The disease is rare in Cuba even today, and he thinks that the diagnosis is often erroneously made both by the present health authorities of Cuba and those during the American Intervention. When the eye disease is unilateral or when it is easily cured, trachoma can be excluded. With time and efforts, trachoma can be exterminated, like yellow fever. It is a poverty and filth disease, and once established, he reiterates, it is never cured, and the diagnosis can be made positively only on the course of the disease.

93 Treatment of Psoriasis. J. S. De Grado.—p. 56.
94 *Treatment of Tuberculous Meningitis. J. M. Bausá.—p. 58.

90. **Acute Mastitis with Chronic Course.**—Nine days after normal delivery the mastitis developed, and the temperature kept febrile for a month, with edema. The latter was ascribed to a toxic action on the heart from the suppurating mastitis, and the leukocytosis of 18,000 compelled a more rigorous search for concealed pus. But there was no retromammary abscess and the whole subsided just as the deeper operation was contemplated.

92. **Influence of Influenza on Pulmonary Tuberculosis.**—Blasco reports that among seventy-two tuberculous outpatients in his charge, with various phases of pulmonary tuberculosis, taking tuberculin treatment, fifty developed influenza during the epidemic but twenty-six seemed to throw it off without harm. In twenty-four, however, the disease was whipped up to a much more active course, invading hitherto sound regions even in 2 of the 14 in the first stage. The tuberculin treatment did not seem to have any mitigating influence on the pandemic disease.

94. **Tuberculous Meningitis.**—Bausá deplores that he has never been able to save a child with tuberculous meningitis in his sixty cases, and yet, he exclaims, it is a local disease; it does not kill by septicemia, and most of the symptoms are the work of the high pressure. The lesions in the meninges are not incompatible with life; the meninges can rank with the peritoneum and the pericardium, and neither peritonitis nor pericarditis are inevitably fatal. We have means to keep the pressure reduced and apply topical treatment. The disease with its apparently acute course, is really subacute or with a chronic tendency. The "acutization" may be from reinfection or lessening of the defensive forces. The cerebrospinal fluid reforms rapidly, so that the relieving puncture must be frequently repeated, and large amounts withdrawn without fear. Or a cannula might be left as a permanent drain and some antiseptic applied directly to the meninges. He has no suggestion to offer yet as to the antiseptic that might be used, but heliotherapy, local heat and antiserums might be used as adjuvants. Tuberculin treatment might prove dangerous with the meningitis well under way, but it might be of great assistance in warding it off if given during the prodromal phase of vague and fleeting symptoms difficult to note and appreciate.

99 Gallstone Cholecystitis and Duodenal Ulcer. Excision. Recovery. N. Tagliavacche.—p. 110.
100 Rhinolithiasis. M. Galdós.—p. 111.

95. **Purulent Peritonitis in Infants.**—Acuña and Causaubon report a case in a child 21 days old. The infection had probably occurred by way of the umbilicus, and the spleen was found ruptured at necropsy. In a second case, the infant was nearly 5 months old and the peritonitis was evidently secondary to enterocolitis. A third infant only 3 weeks old was taken suddenly in the midst of perfect health, and necropsy disclosed stenosis in the small intestine as the only thing to which the peritonitis could be attributed. All the children were breast fed, but the first showed signs of inherited syphilis. Hydrocele is frequently encountered in such cases, with edema of the scrotum, as an early sign of the peritonitis. The stools were normal in two of these cases and there was constipation in the third.

96. **The Treatment of Pulmonary Tuberculosis.**—Barlaro reiterates that tuberculous infection is readily curable, that the organism is able alone to conquer it. What makes it serious is that other infections become installed, against which the organism is powerless, or the organism is allowed to become so saturated with toxins that it is unable to keep up the fight. There is no need for search for a remedy to cure tuberculosis. What we must seek are means to act on an organism saturated with the tuberculous toxins, and to act on the associated infections. The main point is to strengthen the organism in its fight against tuberculosis before it has become so impregnated with the toxins. He urges efforts to diagnose the tuberculous infection before it becomes localized in any point or organ, and before the tubercle bacillus has reached the stage of the Koch bacillus. In this stage it is resistant to all measures and is unable to serve as an antigen. This is partly on account of its resistant shell and partly because by this time the organism is too much debilitated to be able to manufacture antitoxins to any amount. Tuberculous infection attacks every one practically, and usually the organism conquers it alone and is left more resistant to later infection.

104 Popliteal Aneurysm. Trias Pujol.—p. 180.
105 Influenza. P. Esquerdo and others.—p. 185; p. 189.

101. **Palography.**—Gil-Casares gives a number of typical photographic reproductions of the pulse obtained with his palograph. With this it is possible, within certain limits, to estimate the force of the pulse besides the rhythmic aspect, as he explains in detail.

102. **Eclampsia.**—Proubasta analyzes the different theories that have been advanced to explain the pathogenesis of eclampsia, citing various authors. The only certain findings to date, he says, are that the liver is usually and most particularly affected; that there is profound toxemia, and that a substance is found in the serum which acts like epinephrin and resembles the amins, especially those of pituitary origin.

103. **Hypochondriac Ideas.**—Juarros means by this term an exaggerated or baseless preoccupation in respect to the health. Some consider it the result of abnormal sensations of visceral origin, or the abnormal exaggeration from autosuggestion of a normal sensation. The constitutional hypochondria should be distinguished from the occasional, and with the latter, the cases of mental origin must be distinguished from those which have some somatic foundation that may be sought and removed. In short, he declares, the complaints of a hypochondriac deserve serious attention instead of being disregarded as is often the case.

112 *Influenza and Ophthalmology. R. Guiral.—p. 557.
113 Teratosoma Monster. R. M. Orihuela.—p. 559.

110. **Aprosexia of Nasal Origin.**—Segui remarks that inability to concentrate the attention, as a consequence of mouth breathing, is not restricted to children. He reports the case of a woman of 36 and of a man of 41, both of whom suffered from physical and psychic depression and aprosexia from the obstruction to normal breathing and hence accumulation of toxic wastes in the body. The woman had frequent headaches and had lost all her energy, both physical and mental. The inferior turbinates showed such congestive hypertrophy that they almost totally obstructed the passage of air. He reduced both with the actual cautery and gave a little strychnin. In three weeks after the last cauterization the passage was normally permeable and the woman's general condition was normal once more. The man did not have headaches but for over a year had felt incapable of any sustained effort or clerical work. After removal of some obstructing polyps in the nose, normal conditions were restored. In Havana the medical inspectors order an operation for schoolchildren who are mouth breathers.

112. **Ocular Complications of Influenza.**—Guiral found the influenza bacillus constantly in the numerous recent cases of what seemed to be Week's conjunctivitis except that the patients complained of blindness. The redness is not diffuse; there seemed to be a narrow space around the cornea before beginning of the hyperemia. The fibrinous secretion was not suppurative, and there was no pain, no sensation of sand in the eye, but the eyelids and region were puffy. One man of 50 had both corneas ulcerate, with rapid destruction of tissue. The influenza bacilli and the pneumococcus were cultivated from the secretions of the eyes. There was no pain in the eyes, but the general symptoms of influenza were marked. Guiral cauterized the ulcerations and applied a 1:40 solution of zinc sulphate twice a day, but vision in one eye was lost completely. *Almost all the cases had more or less ulceration of the cornea.*

116 *Ozena. I. F. Seco.—p. 321.

114. **Influence of Physical Exercise on the Arterial Pressure.**—Bañuelos and Portela tabulate the findings in tests of boys and young men before, during and after exercising in a gymnasium. They found that moderate physical exercise reduced the arterial pressure, and that this reduction was more pronounced the less the training of the subject. Violent physical exercise raised the pressure.

115. **Limits for Braxton Hicks Version with Placenta Praevia.**—Villanueva's conclusions from his extensive experience are that with vertex presentation this procedure should be restricted to emergency cases with much loss of strength from hemorrhages during the latter part of pregnancy, compelling rapid termination of the pregnancy. Outside of these conditions, and when the condition is not very grave, he thinks that other measures will generally answer the purpose. Tamponing the vagina after rupture of the membranes has often modified conditions favorably in his experience. Although the gauze does not come in contact with the bleeding point, yet the stimulus from its presence is felt throughout the uterus and the contractions assume a new character, the head descends and blocks the bleeding vessels, and the projecting part of the placenta is pushed along out of the way. This can be hastened by injection of pituitary extract, which reenforces the stimulus from the tampon.

116. **Ozena.**—Seco reports favorable experiences with an autogenous vaccine in some cases of ozena. He began with a stock vaccine, and this alone answered the purpose in some cases, but in others he supplemented it with the autogenous. It seems to sterilize the nasal fossas, and by inducing more copious secretion in them clears them of crusts and there is no further tendency to fetidity.

125 Tuberculin in Diagnosis and Treatment. J. J. Vitón.—p. 347.
126 *Morbid Associated Movements. C. S. Damel and A. Natale.—p. 352.

117. **Chemistry of Gastric Juice.**—Landolph here describes (in French) his research on the diverse fractions of distillation of the gastric juice of dogs, demonstrating, with precision, by weight, the chlorin obtained in the form of silver chlorid. The first fractional distillate does not modify litmus paper, and hence cannot contain more than traces of chlorin. There is no acid reaction until the gastric juice begins to decompose. He compares the findings with his technic with those of the Hayem-Winter method.

118. **Treatment of Amebiasis with Pomegranate Bark.**—Vaccarrezza does not venture to pass judgment on this treatment but merely reports two cases in which the infusion of the pericarp of a pomegranate was given by the mouth in a pint of milk, and an infusion of the bark of two was given in an enema to be retained. A clinical cure was realized in each case and the stools of one patient now are free from amebas. The other has been lost to sight.

124. **Abscess in Side of Pharynx.**—Castilla reports two new cases, bringing to four his record of lateropharyngeal abscesses. In each case the child developed suddenly fever and extreme prostration, with difficulty in swallowing and moving the head, and the neck looked swollen and was tender. In six or eight hours from the first symptoms a tumor was evident in the side of the pharynx. In all his cases the whole clinical picture promptly retrogressed in from twenty-four to thirty-six hours under hot applications, disinfection of the nasopharynx and injection of a vaccine (Mendez' haptinogeno neumo). No surgical measures seem to be necessary. His fourth patient was a 3 months babe, and lumbar puncture had been done on suspicion of meningitis.

126. **Associated Morbid Movements.**—Damel and Natale describe four new cases of involuntary movements of jaws or eyelids associated with chewing or speaking movements. One case was in a healthy married man of 24 with ptosis of the right eyelid from birth. When told to open his mouth wide, the eyelid rises symmetrical with the other eye, as also when he twists his jaw to the left.

130 *Research on Dynamics of Heart. M. B. Garcia.—p. 737. Conc'n.

127. **Prophylaxis of Malaria.**—This is a detailed report on the measures that should be adopted to ward off malaria in the public works now under way in Aragon. The chief engineer has appealed to the Instituto Nacional de Higiene, of which Ramon y Cajal is in charge, to aid in stamping out the endemic malaria which has already incapacitated a number of the workmen.

128. **Pathology and Exploration of the Mediastinum.**—Quesada analyzes five different types of findings in the mediastinum and the differential diagnosis therefrom. The arteries usually escape compression, but the veins are liable to be compressed at different points, with widely different disturbances resulting. Compression of nerves is liable to induce a spasmodic cough, attacks of dyspnea, recurrent paralysis, bradycardia, nausea or diarrhea, all of which were represented in the cases described. There is also liable to be spasm of the glottis, respiratory arrhythmia and hyperacidity as manifestations of pressure on the pneumogastric nerve. Pressure on the sympathetic may likewise induce exophthalmos, partial sweating, tachycardia, psialorrhea and lacrimation. Uneven action of the diaphragm and phrenic neuralgia may also be observed. Intercostal neuralgia from pressure on intercostal nerves is more common. The symptoms from compression of vessels are more pronounced when the anterior mediastinum is involved; symptoms from the air passages and esophagus with involvement of the posterior mediastinum, and the liability for pain to develop is greater with the latter. In one of the cases a tuberculous process in lung and ganglia masked an aneurysm of the aorta although it might have been suspected from the spasmodic cough, the pains darting to shoulder and arm, and the history of old syphilis. In another case a man of 39 developed edema of the neck and face, with collateral circulation over chest and umbilical region, tachycardia, psialorrhea, exophthalmos, lacrimation and rebellious diarrhea. This combination of symptoms suggested pressure on the sympathetic nerve, and radioscopy revealed a tumor, evidently malignant.

129. **Professional Blunders.**—Sanz records some historical instances of bad luck pursuing some of the most noted physicians of different ages, or their professional blunders.

130. **Dynamics of the Heart.**—Garcia has been conducting research on the chronotropic influence exerted on the heart by stimulation of the pneumogastric. In this concluding installment he describes the various effects produced according as the ventricle is more or less filled and beating in isometric contraction. The filling of the ventricle, even partially, modifies the effect in a most pronounced manner.

134 *Gumma in Orbit. A. A. M. Nelissen.—p. 1183.
135 Cerebral Symptoms in Influenza. J. Lankhout.—p. 1187.

131. **The Chin and Speech.**—Van den Broek is professor of anatomy at the University of Utrecht, and he here discusses the evolution of the chin as a consequence of spoken language. Only when articulate speech became possible were human beings able to manifest their feelings and thoughts to each other, and then began the rapid upward rise. The muscular movements which the use of speech entailed modified the shape of the chin to what we see now.

132. **Associated Spinal Cord Disease.**—Meinema relates that in the course of a few months recently he encountered three cases of combined funicular myelitis. Examination of the blood gave typical findings in all, but there was anemia enough to attract attention only in one of the three cases. This emphasizes the necessity for examining the blood as a routine procedure in every case of spinal cord disease. In one of the cases the only symptoms had been mental, and the discovery of a grave organic spinal disease was a surprise. Delirium, apathy or somnolency have been noted in different cases. A hysteriform set of symptoms sometimes ushers in the trouble. Degeneration of the posterior tracts entails atony, loss of certain reflexes and ataxia, while degeneration of the lateral tracts entails increased tonus, exaggerated reflexes and motor weakness. The combination of the two thus induces a picture that it is easy to imagine, the symptoms of tabes or of spastic spinal paralysis obtaining the upper hand as the case may be. This combination, however, is very rare. His patients were a woman of 29 and two men of 40 and 51. Tabes was the first presumptive diagnosis, but the Wassermann reaction was negative. There was nothing

in the history to suggest a toxic pseudotabes. The blood count in the three cases showed from 1,992,000 to 2,500,000 reds, with a color index of 1.8, 1.35 and 1.75; from 3,500 to 4,500 whites, with 71 per cent. neutrophils and 21 per cent. lymphocytes in the woman. One man showed 75 per cent. polymorphonuclear leukocytes and 25 per cent. lymphocytes. Only one of the three has died and necropsy was not possible in this case. The lesions responsible for the symptoms evidently did not extend into the brain. He analyzes the literature and emphasizes that these changes in the spinal cord do not occur exclusively with pernicious anemia. They have been encountered associated with leukemia, septicemia, ulcerative endocarditis, malaria, cancer, diabetes, tuberculosis, alcoholism, lead poisoning, Addison's disease, pellagra and paralytic dementia. The degeneration in most cases seems to follow the blood vessels. Henneberg thinks that some hemolytic toxin is probably involved which acts to induce both the anemia and the funicular myelitis. The anemia is not always of the pernicious type. MacConnell reported in 1907 a case in which, after a severe hematemesis, atrophy of the optic nerve developed and the combined spinal-cord tracts affection. The latter retrogressed in time, but the optic atrophy persisted. Von Hasselt's case is also instructive, the patient suddenly presenting the symptoms of the combined tracts affection after a severe hemorrhage from a tubal abortion. The woman died in a day or two, but nothing pathologic could be discovered beyond intense anemia of the tracts. Evidently death had occurred before histologic changes had become manifest. If toxins are responsible, we would expect to find the most pathologic changes in the more vascular regions, but this is not the case. The regions with the poorest blood supply seem to suffer most, and these would naturally feel most severely any depreciation in the quality of the blood, and, in these regions, the parts would suffer most which are worn out most.

134. **Tumor in Orbit.**—The woman of 42 complained of disturbance in vision in her left eye. She was fitted with glasses but returned in two weeks with the eyeball protruding from the rapid growth of a tumor. It seemed to be a phlegmon in the orbit, secondary to empyema of the maxillary sinus, but the sinus when opened was found free from pus. Roentgen treatment was applied while potassium iodid was given daily. The tumor in the orbit rapidly retrogressed and the prompt and complete recovery confirmed the assumption of syphilis. The woman's four healthy children and the history of the family explained the case as one of tardy inherited syphilis. The Wassermann reaction had been negative. The inflammation in the maxillary sinus seemed to be a casual secondary infection.

140 Complications of Distortion of the Knee. H. B. Dahl.—p. 1289.

136. **Nonsyphilitic Mental Disease in Syphilitics.**—Wimmer reviews the present status of our knowledge of the manifestations of syphilis in the nervous system, especially simple syphilitic psychoses. Those of the exogenous type resemble those with typhoid, malaria, alcohol, cocain, carbon monoxid, poisoning and diabetes, uremia, hyperthyroidism, etc. But when we encounter the endogenous form, periodic exacerbations of an inherited constitutional anomaly, of the manic depressive type or the various forms of paranoid, we must be very cautious in accepting a syphilitic origin. The probability is that it is a casual coincidence. In a case described, the man of 25 had presented symptoms of a tendency to dementia in the last few months, five or six years after contracting syphilis which had been given systematic treatment. The strong reactions in the spinal fluid, the connection with neurologic symptoms, and the subsidence of the dementia under specific treatment confirmed the assumption of a transient functional psychosis. Twelve other cases are described with full details in which mental symptoms of hysteria coincided with nervous manifestations. In the second stage of syphilis in one woman of 29, the clinical picture was very puzzling; dementia was assumed at first. In some other cases there was an attack of mania before the infection with syphilis. Necropsy confirmed the assumption of an old endogenous manic-depressive psychosis with recent syphilitic meningitis or paralytic dementia. In another case the paranoid psychosis with hallucinations seemed to be an exacerbation of a pronounced psychopathic constitution for which the unmistakable cerebral syphilis could not be held responsible. The cases reported demonstrate that even with the four syphilitic reactions positive in the spinal fluid, it does not follow that the psychosis observed is necessarily of syphilitic origin. At the same time, this is the general rule, and the reactions in the spinal fluid can usually be relied on. Coincidence of nonsyphilitic psychoses with cerebral or meningeal syphilis is very rare.

137. **The Stomach with Gallstone Disease.**—Wessel examined the stomach findings after different test meals, and with the roentgen rays in 205 persons with gallstones. An operation was done on 5 of the men, 70 of the women and one child. Among the points thus established was the reduction or complete suspension of production of hydrochloric acid when the gallbladder functioning was arrested. Hypochylia or achylia seems to be very frequent with cholelithiasis, and it seems to persist. Gastritis probably develops in time, rendering the achylia irreparable. It seems to be a reflex phenomenon and it is his impression that achylia is the rule after cholecystectomy. In his forty-one cases in which the stomach findings were investigated in cases of infectious processes in the biliary passages, hypochylia or achylia was the rule. The question as to the possibility of reflex achylia seems to have been definitely decided by this research. The discovery of this reflex achylia calls for prompt operation on the biliary passages before irreparable lesions are installed, and, further, it warns not to remove the gallbladder if it is in any way possible to save it. Rovsing has long combated the tendency for cholecystectomy, and these researches show that with this operation we may leave our patients with a permanent stomach affection. The achylia is an indication for a gallstone operation not only to ward off an irreparable gastritis, but because the bile passages seem to become infected more readily when gastric secretion is below par.

Wessel's statistics are not large but they are so conclusive, he says, that he marvels that greater attention has not been paid hitherto to the connection between achylia and infectious processes in the biliary apparatus. Another practical point emphasized by his research is that oil treatment and saline purgatives are contraindicated when there is achylia. In a number of his patients the achylia was what first gave the clue to the cholelithiasis. It is possible that some of our patients whom we have been treating for gastritis alone, may have unsuspected gallstones. Fluctuations in the hydrochloric acid content of the stomach are instructive, as also variable retention of the stomach content. In some of his cases the gallstones were evidently responsible for the eight hours' retention after a Bourget-Faber test meal. Roentgen examination usefully supplements the other tests, revealing possibly four hours' retention or a displacement of part of the stomach pulled aside by pericholecystitis processes. By these means we can detect the presence of gallstones that never have given rise to colics. A gallstone does not entail urobilinuria when it is resting, but any obstruction from it entails stasis of bile, and this is revealed by urobilinuria unless the obstruction is total. The jaundice and the clay colored stools are not so instructive as to complete obstruction, as the sudden disappearance of urobilin from the urine. The discovery of achylia, with a contemplated gallstone operation, warns against delay to save the stomach from further damage.

VOL. 72, NO. 2 CHICAGO, ILLINOIS JANUARY 11, 1919

THE SIGNIFICANCE OF TUBERCULOSIS IN INFANTS AND CHILDREN

WITH MEASURES FOR THEIR PROTECTION *

ALFRED F. HESS, M.D.
NEW YORK

One of the most important advances in recent years in connection with the study of tuberculosis has been the realization that human infection by tubercle bacilli takes place usually during infancy or early childhood. If we consult medical treatises written forty or fifty years ago we find it stated that infants rarely are subject to tuberculosis: accordingly, this aspect of the disease is dismissed with scant consideration.

To von Behring belongs the credit of focusing our attention sharply on this new aspect of the problem—an attention which has been allowed gradually to lag and wander. If we are to benefit to the full by this new knowledge in our arduous fight against this disease, concentrated study should be devoted to gaining a comprehensive understanding of all that pertains to infection at this period. It is evident that such knowledge primarily includes a clear conception of the sources of infection, of its frequency at various ages, and of the several factors that tend to influence its clinical course.

Almost all mortality statistics dealing with tuberculosis calculate the death rate according to one of the two standard methods: either in relation to the mortality from other diseases at the same age period, or in terms of deaths per thousand or ten thousand living individuals of the same age. When the former, or "comparative method," is carried out in regard to the first year of life, tuberculosis is compared principally with the large volume of deaths due to prematurity and to diarrheal and respiratory diseases. Such a comparison may readily lead us into the error of considering it a disease of minor importance. This method of assigning each disease its relative rather than its absolute status is valuable for those who are making a study of a particular age period. In the case in point, for example, it is of interest to those concerned solely in infant welfare. It may lead us far astray, however, if we desire information as to the actual importance of tuberculosis in the early years of life, in order to ascertain whether it constitutes a serious problem in combating this disease. A similar criticism holds true, to a less extent, when we consider the deaths from tuberculosis in their ratio to living individuals. Manifestly there must be more people alive under the age of 1 year than in any other one year period. Accordingly, an equal number of deaths from tuberculosis will appear less numerous and important at this time of life if calculated on such a percentage basis. It is clear, therefore, that we who are interested in investigating tuberculosis will not come to a clear understanding of our problem by adopting either of these statistical points of view. It will be advisable for us to ascertain in absolute numbers how many deaths occur year by year, or period by period, in order to obtain a true concept of the ravages of this disease.

GREAT MORTALITY IN FIRST YEAR OF LIFE

With the cooperation of Dr. Guilfoy, registrar of the Department of Health of the City of New York, I have prepared tables designed to throw the subject into relief from this point of view. The first table gives the absolute number of deaths from tuberculosis at different ages in Greater New York for the past five years (Table 1). A glance shows the large number of deaths from tuberculosis during the first and second years of life, and further study brings out the *striking fact that the* deaths during the first year of life exceed those of any other year excepting the period between 35 and 40. When we take into consideration the great difficulty in diagnosing tuberculosis in the infant, and the number of cases that doubtless are mistakenly registered as congenital debility (a group that comprises over one quarter of the deaths of infants under 1 year), it would seem no exaggeration to state that *deaths from tuberculosis in no one year exceed those of the first year of life.* It is evident, therefore, that, in our efforts to combat tuberculosis, attention should be directed to the infant.

TABLE 1.—DEATHS FROM TUBERCULOSIS IN NEW YORK CITY (1913-1917) ACCORDING TO YEARLY PERIODS

Age Period (Year)	Pulmonary	Other Forms	Total
0- 1	205	1,064	1,269
1- 2	181	967	1,151
2- 3	98	604	702
3- 4	81	359	440
4- 5	74	280	354
5- 9*	63	134	197
10-14	114	54	168
15-19	514	72	586
20-24	938	78	1,016
25-29	1,069	78	1,147
30-34	1,110	62	1,172
35-39	1,397	59	1,356
40-44	1,058	71	1,129

* Figures after 5 years of age are averages of quinquenniums.

A consideration of the mortality from tuberculosis during childhood naturally leads to the inquiry as to when the children become infected; it calls for statistical information in regard to infection. There have been many studies of the frequency of tuberculosis infection in childhood, especially since simple methods of applying the tuberculin reaction have come into vogue.

---

* Read before the Trudeau School of Tuberculosis, Saranac Lake, July 17, 1918.

One of the most thorough inquiries of this kind has been carried out during the past two years by Dr. Bass[1] at the Home for Hebrew Infants, an institution harboring about 400 children under 6 years of age. It should be borne in mind that children of this kind come from the poorest quarters of the city, and therefore cannot be considered representative of the entire urban population. Bass found in over 1,000 tests that 7.8 per cent. of the infants under 6 months of age reacted positively to tuberculin, that 15.8 between 6 and 12 months reacted, and that 75 per cent. of the children between 5 and 6 years gave a positive reaction (Table 2).

These percentages may impress one as exceedingly high, and, in point of fact, are higher than those reported by many others. On the other hand, we find that Calmette[2] and his co-workers found that 8.7 per cent. of infants under 1 year had a tuberculous infection, and that Kaspar[3] placed this figure at 10 per cent. A single von Pirquet test would not lead to these results. If, however, multiple tests are made and the intracutaneous method (Mantoux) is employed, a far larger number of positive reactions will be elicited than when reliance is placed on a single cutaneous test. For the tests to which we have reference, three cutaneous as well as three intracutaneous inoculations were made at appropriate intervals.[4]

TABLE 2.—AGE DISTRIBUTION OF PATIENTS REACTING POSITIVELY TO CUTANEOUS OR INTRACUTANEOUS TEST

Age	Number Tested	Reacting Positively	
		Number	Per Cent.
0-6 months	51	4	7.8
6-12 months	38	6	15.8
1-2 years	29	5	17.2
2-3 years	45	14	31.1
3-5 years	28	12	42.8

After the first two years of life, a quiescent period gradually begins to set in as regards the development of clinical tuberculosis. We also find year by year that fewer children die from this disease (Table 1), notwithstanding the fact that, as just mentioned, the number of infections steadily increases. Another change to be noted is that, whereas during the first few years of life there are comparatively few deaths from pulmonary tuberculosis, the great majority being due to meningitis, at about 10 years of age this relationship is reversed, and from this time forward the great majority of deaths are due to pulmonary involvement.

There is a second active phase in the development of tuberculosis. This is usually associated with the quinquinquennium from 10 to 14 years, and has been recognized for some time. It was brought out some years ago by Guilfoy,[5] who showed that the death rate from tuberculosis in New York City in 1907 had increased during this age period as compared with that in 1867. It is a subject which has been emphasized recently in an excellent report by Dublin[6] on the mortality of childhood. We shall consider it later in detail.

EXPOSURE AND SUSCEPTIBILITY

What is the cause of these periods of exceptional mortality? Let us first take up the period of infancy, and study the factors which during these first years of life predispose to death from tuberculosis. These may be summarized as increased exposure, heightened susceptibility, or a combination of these two factors. There can be no doubt that, when a tuberculous mother or nurse cares for an infant, it is exposed to infection to a degree far greater than are the older children of the household. Close contact under such conditions renders escape from infection almost impossible, so that it can be accepted as axiomatic that marked exposure plays a rôle in the high mortality that we have recorded. There is, moreover, the double danger of frequent infection and of transmitting a large number of tubercle bacilli—the natural result of the fondling of a baby by a tuberculous person. This question of the dosage of the infecting agent is probably one of the most important factors bearing on the tuberculosis of infants. It is thoroughly appreciated by those who have devoted thought to this subject that, as the result of the intimate contact, the infant must take in a large number of tubercle bacilli. It is not, however, generally appreciated that the quantity of bacilli is large, not only from an absolute point of view, that is, in point of numbers, but also relative to the size of the infected individual. In animal experimentation we note carefully, not only the amount of virus with which we inoculate an animal, but also the weight of the animal inoculated. It is probable that, in general, the same laws hold good in relation to human infection. If such is the case, we must bear in mind that an infant weighing from 8 to 15 pounds and taking in an average number of bacilli, is receiving relatively ten to twenty times the dose of an adult. The size of the host is relatively ten to twenty times smaller.

In addition to the factor of high dosage it is generally admitted that infants are peculiarly susceptible to tuberculosis, causing the infection to run a particularly rapid course. This phenomenon is commonly attributed to the fact that infants furnish virgin soil for the tubercle bacillus, not having acquired any immunity as the result of previous infection. This explanation for their marked vulnerability, which is unquestionable, should not be allowed to pass unchallenged. If this were the full explanation, we should expect that an older child, one of 5 or 10 years of age, who is infected for the first time, should likewise develop progressive tuberculosis. Such, however, is not the general experience. Some years ago a tuberculous nurse in an infant asylum infected a group of children from 3 to 5 years of age.[7] Many of these young children, who previously had repeatedly given a negative reaction to tuberculin, developed a positive reaction within a short period. In other words, they were infected for the first time at this age, having lived in the sheltered surroundings of an institution. None of them, however, developed tuberculous meningitis or other active form of tuberculosis, such as would certainly have occurred had this unfortunate accident taken place during the early months of their lives. It would seem that age brings with it a certain degree of immunity, just as it does in scarlet fever, diphtheria and some other of the infectious diseases. It may be that in addition to a specific immunity, there is a general immunity, brought about by the various infecting viruses, and that the particular susceptibility of infants to tuberculosis is due in part to the fact that their tissues have never had to react protectively to pathogenic bacteria.

[2] Calmette, A., quoted from Jeanneret, L.: La tuberculose de l'enfant, Paris, 1915.

[3] Kaspar, K., quoted from Jeanneret (note 2).

[4] Although the intracutaneous test is more delicate than the von Pirquet test, it should not be taken for granted that, if the former is negative, the latter in all instances must likewise be negative. We have encountered cases which gave no reaction to repeated intracutaneous injections but responded to the skin test. This aspect of the tuberculin reaction deserves further study and elucidation.

BOVINE INFECTION

In an analysis of the causes leading to the high infantile mortality, another factor has to be considered which is brought about both by exceptional exposure and special susceptibility. I have reference to deaths due to infection of the bovine type of tubercle bacilli. As is well known, this is still a mooted question, some believing with Koch that this agent does not need to be considered in a study of the tuberculosis problem. However, in the comprehensive investigation of human and bovine tuberculosis carried out by Park and Krumwiede,[5] about 15 per cent. of the deaths of children under 5 years of age were due to bacilli which they identified culturally as bovine in type. This, accordingly, is a factor which must be considered in accounting for the high mortality of this period, although it should not be appraised as a preponderating influence. These percentages of bovine infection are sufficiently high to be taken cognizance of from a prophylactic standpoint. They are, indeed, surprisingly great for a city like New York, where such a large part of the milk is subjected to pasteurization. It would seem advisable from time to time, at intervals of about five years, to carry out similar investigations in our large cities, in order to obtain reliable information regarding the prevalence of bovine tuberculosis, and to furnish a sound basis for stricter sanitary ordinances, should the high morbidity and mortality not diminish.

INFECTION FROM LATENT CARRIERS

Opinion is still divided as to exactly how the majority of infants and children become infected with tuberculosis; how it comes to pass, for example, that 43 per cent. of these children between 3 and 5 years of age gave evidence of having taken in tubercle bacilli. In many instances we are able to trace the source of infection of clinical tuberculosis in infants, of tuberculous meningitis or other active forms of the disease. In the majority of cases the mother is responsible, the father and other members of the household transmitting the disease less frequently. In a considerable number of instances, however, it is impossible, probe as we may, to ascertain the source of infection. This is true in a far greater measure when the infection is very mild and we are dealing with an older child in apparent health, who merely reacts to one or more tests with tuberculin. In my opinion, these children are infected in a manner not essentially different from those in whom the source is traceable, the difference being merely that in the former the focus is unrecognized—that they have been in contact with communicable but undiagnosed tuberculosis. There is a clinical basis for this point of view. It is within the experience of most physicians that persons in apparently normal health may show tubercle bacilli in the sputum. This has come to light even in relation to physicians in the course of a casual examination of their own sputum. It seems probable that there are many individuals who from time to time excrete tubercle bacilli, who are occasional shedders, if we may use this term, of tubercle bacilli, and who are responsible for the large numbers of reactors encountered among children tested with tuberculin. It would be of interest and importance, to put this question to a test, to examine the sputum of individuals who from time to time suffer from an apparently negligible cough, making tests daily for a period of months, and using not only stained films, but the more searching method of fluidification and centrifugation of a large quantity of sputum. If this explanation is the correct one, it brings out the immensity of the tuberculosis problem, and, at first glance, may seem to offer a most disheartening outlook. We must remember, however, that, in general, persons with a positive sputum are dangerous in proportion to the number of bacilli which they excrete and only for the period of time during which they are "positive cases." It does, however, emphasize the fact that, where there are young children, we should watch more carefully for communicable tuberculosis among the adults of the household who suffer from apparently harmless catarrhal respiratory infections.

* This table shows that there is a marked increase in the absolute mortality from tuberculosis at about the thirteenth year of life (first column). This sudden increase corresponds to maturity, and, it will be noted, occurs in girls at 13 and in boys at 15 years of age.

SECOND ACTIVE PERIOD

As mentioned above, after the second year of life a remarkable decrease in the number of deaths from tuberculosis becomes evident; a quiescent period sets in which continues with increasing emphasis for a space of about ten years. Then follows what may be termed the second heyday of tuberculosis, a protracted period of high mortality showing no mitigation until the early forties. This marked rise is peculiar to tuberculosis, for the general death rate is, as we should expect, at its lowest ebb at this time of life. In an attempt to define more sharply the onset of this important period, we have compiled statistics showing the number of deaths from tuberculosis year by year in three of our largest cities (Table 3). This shows that the increased mortality begins rather abruptly at the thirteenth year and rapidly progresses (Table 3, last column). When we classify these figures according to sex, we note that this increment is due entirely to an increase in deaths among females; that the deaths of girls from tuberculosis increases markedly at the age of 12 years, whereas a corresponding increase in the number of deaths among boys does not take place until 16 years of age. This shows the fallibility of relying solely on quinquennial periods in tabulating statistics—the mortality of the females falls in the third quinquennium, that of the males in the fourth (Table 4). At the age of 20, for the first time after infancy, more boys die of tuberculosis than girls. A striking feature of this study of the sex factor is the uniformity in the occurrence of the increment, its variability in the three cities for 1916 and 1917 never exceeding one year. In considering these tables we must always bear in mind that the susceptibility to infection must antedate, by at least a year, the mortality from the disease.

45-49	666	206	689	221	661	189	691	201	2,713	823	3,536

How are we to interpret this sudden increase of deaths from tuberculosis? The most convincing interpretation of these figures seems to be that they are governed by the onset of maturity, by the evident but little understood forces that become potent at puberty. No other explanation accounts so fittingly for the sudden and precocious alteration in the reaction of the female to tuberculosis infection, and to the later but equally significant impetus in the mortality of the male.[9]

But if we accept this explanation for the great increase of the disease at this life cycle, we must accept the premise that reinfection has its source probably from within the body and not from without; that it is an autoinfection from an old tuberculous focus. For it is evident that boys and girls are not exposed to infection at this particular age more frequently than at a younger period, when we note that deaths are comparatively few. It is still more evident that girls are not subjected to this danger four years earlier in life than boys. It may be answered that these considerations prove that maturity is an etiologic factor, but that it has merely a predisposing influence, rendering the tissues more susceptible to tubercle bacilli entering from without. But we have seen that there is a remarkable constancy in the year of increase in the mortality in the female as well as in the male, that almost without exception the mortality of the former advances sharply at the age of 12 years and that of the latter at the age of 16. If this is brought about by an intake of tubercle bacilli transmitted by contact infection, we must presuppose that these girls and boys are being infected with tuberculosis every year of their life. In no other way could this uniform periodicity be accounted for. It is more logical to regard this sudden flare up as an activation, at the time of maturity, of some lesion in the bronchial gland or in the lung, which had remained latent from early childhood.[10]

COUNTRY PREVENTORIUMS

It follows, therefore, that tuberculosis is a disease fraught with the greatest danger to child life, and is most to be feared at the extremes of this period. Such being the case, what is being done to cope with this situation, to protect our infants and adolescents? In regard to the former, the following incident is indicative: A few years ago we ascertained the number of infants in the homes of the children who were at that time at the Tuberculosis Preventorium (at Farmingdale, N. J.). This institution cares for children of tuberculous parents, and accommodates about 180 girls and boys between the ages of 4 and 14. It was found that in the 120 homes there were forty-two infants under the age of 2 years who were exposed to infection. On writing to the commissioner of charities of the city of New York acquainting him with this situation, and asking how to protect these infants, he replied, after due consideration, that there was no institution or other provision for this class of case. The hospitals would not accept them because they were not sick; the orphan asylums refused them admission because the parents were living, and the infant asylums because they were not destitute. Accordingly, we established in connection with the institution a small preventorium for infants which has been maintained for the past three years. I shall not go into the details of the working of this endeavor, as a report has recently been published of its activities.[11] It will perhaps interest the reader to learn that we have not encountered any insuperable difficulties in its administration; that mothers will part with their babies for a period of at least a year if they are told of the danger to which they are otherwise subjected, and that the infants have thrived in the institution. There are merely two points which it may be well to emphasize: The first is that to insure success the infants must be separated from their mothers early, before they have been infected, as shown by a von Pirquet test, and second, that, owing to the fact that most of the mothers died during the first year of the infant's life, there rarely has been danger of returning the baby to its dangerous environment. The instances in which the pressure to return an infant to infectious surroundings has constituted a knotty problem have been few, far fewer than we had expected.

---

[9] It is of interest in this connection that reports of the U. S. Department of Agriculture show that of the steers and bulls retained for tuberculosis during the years 1915, 1916 and 1917, only about 7, 6.5 and 6 per cent. of the former were condemned annually against about 10, 10 and 10.75 per cent. annually of the latter. Possibly castration may account for the smaller percentage of progressive tuberculosis among the steers.

[10] The fact that the soldiers develop tuberculosis generally within a month or two of their entrance into active service is probably best interpreted as the fanning into activity, through the stress of hard life, of old foci of disease.

[11] Hess, A. F.: Am. Rev. Tuberc. **1**: 669, 1918.

It would seem that the best way to begin to combat this high mortality from tuberculosis would be to establish preventoriums for infants in connection with the large cities. These institutions should be situated in the country about two hours' train ride from the city.[12] They should be built with many balconies so as to provide for an outdoor life, and should be conducted by children's specialists according to the most approved methods (provided with one or more wet-nurses). The infants should be kept at the institution for at least a year. This central preventorium for infants could well serve as the administrative center for a system of boarding out of infants in the farm houses of the surrounding country, under supervision of the physician and nurses of the institution; babies who were not thriving could be returned to the precincts of the preventorium for special care and treatment. There is good reason to believe that by this means thousands of babies in the large cities, who will be infected by their parents, could be saved and grow up as healthy individuals. This question is particularly opportune and urgent at the present time, when many soldiers will return to their homes having communicable tuberculosis.

The problem of the protection of older children against tuberculosis may likewise be said not to have been seriously considered in the United States. Here and there a disjointed effort has been made to provide for a few children, but the need has not been sufficiently clear to stimulate either those active in the field of tuberculosis or others interested in problems of child welfare to map out a definite program. In France the Gaucher movement was organized in 1907 to carry out prophylaxis against tuberculosis in childhood. This organization, which has grown year by year, sends children to homes throughout the country districts of France, where they are cared for by foster parents for many years. The idea is an excellent one, and the work undoubtedly greatly benefits the children.[13] It provides, however, for children only between the ages of 3 and 13, and therefore does not embrace the two critical periods of tuberculosis. It should be supplemented by measures for the care of infants, and, it would seem, should extend the age limit of its surveillance.

One measure which I would suggest to guard against the tuberculosis of maturity is the establishment of preventoriums throughout the country similar to that at Farmingdale, N. J. Children should be sent to such institutions who are poorly developed and undernourished and give a positive tuberculin reaction. If it is true that infection at this period of life emanates from a focus within the body, then malnutrition should play a dominant rôle in the selection of the cases. These children should be kept in the country for from three to six months. It may be objected that, after a few months in the city, they will have lost the benefit of their stay in the country. Such, however, does not seem to be the case. It is difficult to estimate for how long a period children maintain the benefits gained at preventoriums or sanatoriums because the factor of growth complicates the estimation of weight. It would seem best, therefore, in judging whether they are able to hold their gain, to weigh them six months after they have left the institution, an interval so short as to render growth a negligible factor. We have found recently that more than 90 per cent. of the children who have been at the preventorium held their entire gains in weight after this interval, and that the losses in almost all cases have been slight. The children should be under surveillance for many years following their return to the city, and be sent to the preventorium for a second or third time should their nutritional condition demand it.

As the result of a study of the mortality statistics we must conclude that it is inadvisable to make the age of admission from 4 to 14 years, as the high mortality does not begin until 12 in girls and 16 in boys. In view of the great need for preventoriums it would seem wise to accept girls only from the ages of 10 to 16 and boys only from 14 to 18, in other words, two years before the onset of the high mortality. With this change in the age of admission comes the advisability of providing separate preventoriums for boys and for girls. Finally, it seems possible that some affiliation might be made with agricultural schools whereby these children could be referred to such institutions and thus trained in a permanent outdoor occupation.

This is the Children's Year. The Children's Bureau of the United States Department of Labor has inaugurated this movement in order to conserve the lives and health of children as a measure of national defense. The countries of Europe have realized as a result of the war that the protection of the lives of babies has become more than ever a patriotic duty. It would seem as if those actively interested in the propaganda of tuberculosis might properly join forces with those inaugurated by the government, and focus their efforts on the coming generation to prevent the large wastage due to preventable tuberculosis.

SUMMARY

Statistics of infant mortality that show the ratio of deaths from tuberculosis compared to other diseases do not give a true conception of the importance of tuberculosis at this period of life. To arrive at a better understanding of this problem, we must prepare figures showing the absolute number of deaths annually. We then find that in no one year do the deaths from tuberculosis exceed those of the first year of life. This great loss is due in part to the peculiar susceptibility of infants, in part to the fact that they receive an exceptionally large amount of the infective agent. The dosage is large, not only in an absolute sense, in the number of bacilli conveyed by the mother or other infected individual, but also from a relative point of view, when we consider the comparatively small size and weight of the baby. Bovine infection plays a part that is minor but not negligible. In view of the not inconsiderable mortality that has been shown to be occasioned by the bovine type of bacillus, it would be well if cultural studies of tuberculosis in infants should be carried out from time to time, in order to gain an insight into the degree to which milk employed for infant feeding is contaminated by virulent tubercle bacilli.

---

[12] It is of distinct advantage to have an institution of this kind far enough away from the city for the items of expenditure of time and money to act as a deterrent to frequent visits on the part of mothers.

[13] When we consider that tuberculosis tends to flare up at puberty and to continue to reap a high toll of deaths for many years thereafter, it is evident that statistics reporting the benefit of treatment or of hygienic measures must cover this susceptible period to be convincing and of real value. Very little is demonstrated by reports showing that children discharged from sanatoriums or preventoriums have remained well until 15 or 20 years of age. The crucial test comprises the long span of early adult life.

Following the period of infancy there is a quiescent phase in the mortality from tuberculosis, throughout which the deaths decrease year by year, although the number of infections, as shown by the tuberculin reaction, steadily increases. These infections are due probably to latent carriers, to individuals who from time to time shed tubercle bacilli. A daily examination of the sputum of a series of individuals, carried out carefully and for a period of months, might well be undertaken in order to test the validity of this hypothesis.

There is a second active phase in connection with the mortality from tuberculosis. This is commonly associated with the third quinquennium of life. If we study the deaths year by year, rather than by quinquenniums, we find that this period begins at 13 years of age, and that it is not coincident in females and in males. Among the former it sets in rather sharply at the age of 12, whereas among the boys the flare up does not manifest itself until the age of 16. This distinction was found to hold good for several large cities, and is governed probably by the onset of puberty. This uniform periodicity in the increase of deaths from tuberculosis, taking place in both girls and boys at a definite year of life, leads us to believe that the disease is due to an "autogenous reinfection" from some latent focus, rather than a fresh infection from a tuberculous individual.

Much good could be accomplished in combating tuberculosis both in infants and at puberty by providing country preventoriums in connection with the large cities. In view of the mortality incidence outlined above, it would seem advisable to change the present usage in regard to the older children and to restrict these institutions to girls from the ages of 10 to 16 and to boys from 14 to 18. In this way provision would be made for hygienic measures two years before the onset of the second period of high mortality.

16 West Eighty-Sixth Street.

Health of Food Handlers in New York City.—New York City under its Sanitary Code has a regulation regarding the examination of food handlers, requiring them to obtain certificates of health from the health department. An analysis of the results of the examination of 1,980 of these persons, as set forth in an abstract in the *American Journal of Public Health,* shows that 1,590 of these were males and 390 females; 80.2 per cent. were in the age period between 20 and 44 years; 81 per cent. were restaurant and hotel workers and 16 per cent. were confectioners and bakers. Of the 81 per cent., 44.2 per cent. were waiters and waitresses, 19.6 cooks and 9.1 per cent. dishwashers and kitchen employees. The examination of these cases was very thorough. It was found that 32.1 per cent. of the males and 13.3 per cent. of the females were free from disease or any other condition worthy of mention. But among the diseases and defects found were 10 cases of active tuberculosis, 3 arrested cases and 12 suspected cases; 19 cases of active syphilis and 32 of suspected syphilis, and 6 cases of gonorrhea. The prevalence of this latter disease among women was not determined. There were 370 cases of anemia, 112 cases showing eye diseases, 124 cases of heart disease, 64 of diseases of the arteries, 237 cases of varicose veins, 110 cases of colds and rhinitis, 25 cases of chronic bronchitis, 104 cases of pulmonary emphysema, 208 cases of pyorrhea alveolaris, 288 cases of dental caries, 202 cases of pharyngitis, 62 cases of hernia and 133 cases of flatfoot. Bakers and cooks seem to suffer particularly from cardiovascular disease, anemia, flatfoot and respiratory disorders.

THE EFFECT OF HEAT ON THE SPORES OF BACILLUS BOTULINUS

ITS BEARING ON HOME CANNING METHODS: PART 1[*]

GEORGINA SPOONER BURKE
STANFORD UNIVERSITY, CALIF.

There are four methods commonly used in the home for canning fruit and vegetables. They are:

1. The hot pack method, in which the fruit and vegetables are cooked in the open kettle till done and then sealed in clean jars while hot.
2. The cold pack method, in which the fruit or vegetables are first blanched, then packed in jars and the jars put into water and boiled for one continuous period of from one and a half to five hours.
3. Intermittent or fractional sterilization, the fruit or vegetables being packed cold in the jars and the jars placed in water and boiled from fifteen to sixty minutes on each of three successive days.
4. Pressure canning, in which the filled jars are sterilized with steam under pressure.

Of these methods the first two are probably more generally used because they require no special apparatus as for pressure canning, and the work is completed in one day, whereas the fractional method requires three days.

The latest books on bacteriology state that the spores of *B. botulinus* are easily killed, a temperature of 80 C. (176 F.) for sixty minutes being sufficient. If this statement were true of all strains of *B. botulinus,* any one of the four methods of canning mentioned would be amply sufficient to sterilize fruit or vegetables contaminated with *B. botulinus,* and development of toxin in jars would indicate gross carelessness on the part of the cook.

Seven cases of botulism were investigated by Dr. E. C. Dickson of Leland Stanford Junior University School of Medicine during the winter of 1917 and 1918, and in four of these cases I succeeded in isolating *Bacillus botulinus,* either from dead chickens, sick hogs or directly from the cans of fruit or vegetables. In two of these cases, vegetables were canned by the cold pack (one period) method. One of the cooks stated positively that she had kept the filled jars in a covered boiler with the water actively boiling for three hours. She did not, however, blanch the peas before placing them in the jars. In the third case of poisoning the beans were canned by the fractional method, and in the fourth case, in which the poisoning of eight persons followed the eating of canned apricots, the fruit was cooked in the open kettle and sealed, while hot, in the jars. As the cook was one of the first victims, there are no data as to just how long the fruit was cooked.

In view of these conflicting data, a series of experiments were begun to determine the effect of heat on the spores of *B. botulinus.* The work is being carried on under a special grant from the State Council of Defense of California, and has been performed in the Laboratory of Bacteriology and Immunity of Leland Stanford Junior University, where Dr. W. H Manwaring has generously facilitated the work in every way.

There are in this laboratory ten strains of *B. botulinus.* Strains I and II came from the Museum of

---

[*] Report of the Botulism Research of the State Council of Defense of California, July, 1918.

Natural History, New York, and Columbia University, respectively, and I do not know where they were isolated. They produce very weak toxin and their colony formation is not uniform. Strains III, IV and V were isolated by Dr. Dickson from cases of botulism occurring in California and Oregon in 1916 and 1917. Strains III and IV produce a strong toxin and characteristic colonies. Strain V produces a weak toxin and its colonies are not uniform. Strain VI was isolated from cheese in Massachusetts. It produces strong toxin but its colony picture is not uniform. Strains VII, VIII, IX and X were isolated by myself during the past winter from the cases investigated by Dr. Dickson.[1] Strain VII came from Seattle, and the other three from California. They all produce strong toxin and form characteristic colonies. By means of toxin-antitoxin tests it has been shown that Strains III, IV, VII and IX belong to one homologous group, and that Strains VI, VIII and X belong to another. The relationship of Strains I, II and V has not been determined, as the toxin produced is very weak.

Spores develop most rapidly and abundantly in a culture medium made of sheep brains, cooked slightly with a little water and squeezed through cheese cloth. The medium is oil stratified in the tubes. In these cultures the spores are present in the fluid portion and also embedded in the brain tissue. In broth cultures, spores are formed very slowly, and for this reason only two experiments have as yet been performed with broth spores.

Each culture was examined in a smear, stained by Gram's method, and only those cultures were used that were found to contain free spores. Cultures showing only terminal spores were not used.

TECHNIC

Spore Mixtures.—For the broth spore experiments (Tables 1 and 2), about 1 c.c. of the sediment from the bottom of the broth culture was pipetted off with a sterile pipet into a sterile test tube and the volume made up to about 6 c.c. with sterile salt solution.

For the Arnold sterilizer experiment (Table 4), about 2 c.c. of the brain culture were pipetted off with a sterile pipet into a sterile test tube and diluted with about 10 c.c. of sterile salt solution. When the material was boiled in an open beaker (Table 3), about 10 c.c. of the brain culture were mixed in a sterile beaker with about 50 c.c. of sterile salt solution, and loss by evaporation was made up by the addition from time to time of hot sterile distilled water so that the boiling did not stop or the concentration of the fluid change materially. For the autoclave experiments (Table 5) about 0.5 c.c. of a brain culture was placed in a sterile test tube. No salt solution was added.

Apparatus.—Water Bath: A deep pot of water was used for the water bath with a cover having holes through which the tubes were pushed down into the water. The level of the water in the bath was always well above the level of the spore mixture in the tubes.

Arnold Sterilizer: The tubes containing the spore mixtures were placed in a rack in a regular Arnold sterilizer with a double door. The door was necessarily opened for about three minutes during each inoculation period. This, however, was done in a very warm room.

Autoclave: This was of the horizontal type.

Inoculation.—Inoculations were made from the heated material at definite intervals as specified in the respective tables. In all but the autoclave and part of the beaker experiments the inoculations were made by means of small sterile pipets. A separate pipet was used for each inoculation. The amount of material transferred was about 0.1 c.c. This amount was increased somewhat in the inoculations made after the longer periods of heating. For the inoculations of the autoclaved spores, a platinum loop about one-fourth inch in diameter was used. The center of the loop was filled in with a coil of platinum wire to make a scoop so that a very rich inoculation was made. An ordinary platinum loop was used to make inoculations from the foam in the experiment of boiling the spores in an open beaker.

Mediums.—All inoculations were made into tubes of deep infusion or peptic digest agar, 2 per cent. glucose. The agar was boiled for twenty minutes and cooled to 47 C., at which temperature the tubes were inoculated. They were then at once thoroughly shaken and solidified in cold water. They were capped with a mixture of paraffin, beeswax and zinc oxid.

Incubation.—The cultures were incubated in an incubator which varied between 25 and 28 C.

Observation.—The cultures were observed each day for anaerobic growth and gas production. When growth appeared the cultures were examined under the dissecting microscope to determine whether the colonies were characteristic of the given strain of *B. botulinus.* This was done in order to rule out possible contamination with other organisms.

EXPERIMENTS AND RESULTS

Two experiments were performed in which spores from broth cultures were used. The spores were heated in a water bath. In the first experiment (Table 1) the temperature of the water bath was approximately at 80 C., and the temperature inside the test tubes was maintained between 79.5 and 81 C. during the two hours. In the second (Table 2) the water in the bath was kept actively boiling and the temperature in the test tubes was maintained at 100 C. throughout.

* In the tables, + indicates growth; ⊕ indicates growth and gas. Arabic numerals followed by "d" indicate the number of days of incubation before growth and gas appeared in the agar cultures.

Normal cultures of *B. botulinus* in agar grow and produce gas in from twenty-four to forty-eight hours, the more thickly seeded cultures showing up more quickly than thinly seeded ones. In Table 1 it will be observed that the broth spores of five strains survived a temperature of 80 C. for two hours and that 90 per cent. of the cultures developed in from twenty-four to forty-eight hours, while the others showed up on the third or fourth day. It is evident, therefore, that the spores were practically uninjured by exposure to a temperature of 80 C. for two hours. Of the broth spores heated to 100 C. (Table 2), one strain survived after an exposure of fifteen minutes, another after twenty minutes, a third after thirty minutes and a fourth after sixty minutes. The control cultures and some of those inoculated after five and ten minutes' exposure developed in normal time. But the development of the other cultures was retarded. The incubation period was increased in direct proportion to the length of time the spores were exposed to the heat.

---

[1] Dr. E. C. Dickson has a report of these cases in process of publication.

60	100	......	......	......	+15 d ⊕17 d
90	...	......	......	......	......
120	...	......	......	......	......

These two experiments parallel two which were made by Dr. E. C. Dickson[2] and myself last spring with spores from brain cultures. It was found at that time that spores from brain cultures of six strains survived a temperature of 80 C. for three hours and that growth appeared after a practically normal incubation period, and also that spores from brain cultures of five strains, exposed to a temperature of 100 C. for two hours, survived for the entire two hours, while the sixth strain survived for one and one-fourth hours. The negative cultures were not kept more than three weeks. The incubation period of the spores following exposure to 100 C. was increased in direct proportion to the length of time of exposure. Comparing these data with those in Table 2, it is evident that broth spores are somewhat less resistant than those grown in brain mediums, but that they are more resistant than has been hitherto reported.

In all experiments in which spores were exposed to temperatures of 100 C. or over, the subsequent development of the heated spores was more or less retarded (Tables 2, 3, 4 and 5). The longest period of incubation recorded in these charts is fifty-three days (Table 5, Strain X).

The cultures remain apparently sterile for days. No growth is visible even with the use of a dissecting microscope. Then suddenly, within a twenty-four to forty-eight hour period, normal growth and gas production take place. There is a good deal of variation in the resistance of the spores of the different strains to heat and the amount of growth inhibition caused by exposure for any given time. For any one strain, however, the amount of inhibition varies directly with the length of exposure. An examination of the incubation periods noted for each of the cultures in the accompanying tables shows that there are very few exceptions to this rule. Several occur in Table 1; but, as I have already stated, all the cultures in this experiment developed in practically normal time, and the variations that occurred are due to difference in the thickness of seeding rather than to the effect of the heat. In Table 3, Strain VIII, there is a very decided break in the sequence between the spores heated for 150 minutes and those heated for 180 and 210 minutes. But, as will be explained more fully later, the early development of the 180 and 210 minute cultures was probably due to the accidental admixture of foam from the side of the beaker which had not been subjected to the same degree of heat as the liquid at the bottom.

The recognition of the fact that the incubation period of the spores of *B. botulinus* is very much lengthened following exposure to temperatures of 100 C. and over is very important. It means that in testing for the thermal death point all cultures of heated spores that do not show any growth must be incubated for months before they are finally reported sterile. Therefore, whenever negative results are noted in the accompanying tables it must be *understood* that they represent incomplete data and do not indicate the thermal death point of the spores, for none of the cultures have been incubated for more than three months at the time of this writing.

[2] Dr. Dickson has a report of these experiments in process of publication.

It is also very doubtful whether fractional sterilization on three successive days could sterilize spores whose development is so inhibited by exposure to heat. Even exposure for fifteen minutes to a temperature of 100 C. will inhibit certain spores so that they will not develop until the fourth to the tenth day. Two experiments have been performed to test fractional sterilization. In both cases, spores from brain cultures were used and the spores were exposed to a temperature of 100 C. for one hour on each day. In the first experiment, two strains were used, and were heated on three successive days. Both strains survived after the third day's heating. The second time, six strains were tested, and they were sterilized on three successive days and again on the eighth day. Five strains survived the fourth period of heating on the eighth day. The other strain survived after the first period of heating, but so far the later cultures show no growth. The technic of these experiments was not, however, entirely satisfactory, and for that reason a detailed report of them will be reserved until there are more data.

It has been asserted that the blanching of the fruit and vegetables for five minutes in boiling water, as recommended in the cold pack (one period) method of canning, helps to sterilize the material. Also, many housewives can their fruit and vegetables by boiling them in an open kettle and packing them, hot, into clean jars. To test the reliability of these methods for *B. botulinus* spores from brain cultures of three strains were boiled in an open beaker (Table 3). Strain IV was boiled for ninety minutes, Strain VI for three hours, and Strain VIII for three and one-half hours. It was found that as soon as the brain mixture began to boil, a thick foamy scum formed on the surface of the mixture. In a few minutes this broke, leaving a clear portion in the center. For Strain IV, samples of both foam and liquid were taken each time. For Strains VI and VIII, duplicate cultures were made of the liquid and the foam. The foam inoculations of Strain VI were made from the foam adhering to the side of the beaker. For Strain VIII, the foam was taken from the surface of the fluid, except for the 210 minute inoculation, which was made from foam adhering to the side of the beaker.

Strain IV was uninjured by boiling for ninety minutes. Strain VI was uninjured by boiling for three hours, and Strain VIII survived for three and one-half hours, although the development of the spores was much retarded. The four samples of foam from Strain VIII show that the spores in the foam that adhered to the side of the beaker were not subjected to so much heat as those on the surface of the liquid, since the spores in the foam that was taken from the side of the beaker after 210 minutes developed much more quickly than those in the foam taken from the surface of the liquid after ninety and 180 minutes. The comparatively early development of the cultures made from the liquid after 180 minutes' and 210 minutes' boiling is probably due to the accidental admixture of some of the material from the side of the beaker at the time when hot water was added to make up loss by evaporation.

Blanching, therefore, cannot be relied on to kill or even materially injure spores of resistant strains of *B. botulinus*. Its value is as a cleansing agent. And to be effective it should be done before the fruit or vegetables are cut, for spores lodged on the skin may be crushed by the cutting process into the pulp, where they would be protected. The method of canning by boiling in an open kettle and then packing, hot, in the jars and sealing cannot be relied on to sterilize material contaminated with hardy strains of *B. botulinus* unless the boiling be continued for a good deal over four hours. A scum of foam always forms on the surface of boiling fruit or vegetables, and this may contain viable spores for a very long time.

Nine strains were tested in the Arnold sterilizer (Table 4) and ten in the autoclave (Table 5). The spores were obtained from the same set of brain cultures. A set of transplants in agar were made and incubated in order to test out the purity of the cultures.

TABLE 5.—RESULTS OF STERILIZING FREE SPORES FROM BRAIN CULTURES OF B. BOTULINUS IN THE AUTOCLAVE; CULTURES HAVE BEEN INCUBATED FOR THREE MONTHS

Pressure and Time	Time Required for Pressure to Rise, Min.	Time Required for Pressure to Fall, Min.	Strains									
			I	II	III	IV	V	VI	VII	VIII	IX	X
5 lbs.

10 min.	12½	10										
20 min.	10	13	...	...	...	...	...	....	...	....	....	⊕50d
15 lbs.												
5 min.	22½	13										
10 min.	18	16	...	...	...	...	...	....	...	....	....	⊕53d
20 min.	8½	12½										

As these showed typical growth characteristics, no special controls were made for either the Arnold or the autoclave series.

The cultures of Tables 4 and 5 have been incubated for three months. More than half of the cultures are still negative, and none have developed since the fifty-third day. These tables, therefore, represent something approximating the thermal death point of the spores, though some further development may take place.

Spores of Strains VIII and IX survived in the Arnold sterilizer at a temperature of 100 C. for four hours. Therefore, one long period of heating, such as is recommended in the cold pack method of canning, is not a reliable method of killing spores of *B. botulinus.* The internal temperature of jars of fruit and vegetables does not reach 100 C. for about an hour after the surrounding water begins to boil. For these reasons even a period of five hours in boiling water would not sterilize the contents of jars, contaminated with spores of the more highly resistant strains of *B. botulinus.*

A month ago I received a report from a woman who canned a number of jars of string beans a year ago. Nearly the whole pack spoiled in the course of a few weeks. She stated that the beans were cut in pieces, washed carefully in water, packed in the jars, and the jars put in a boiler of cold water, the level of the water being up to the necks of the jars. The water was then brought to a boil and kept boiling for four and one-half hours. Whether any of the spoilage was due to *B. botulinus* is, of course, not known.

The data thus far obtained from the autoclaved spores show that a pressure of 15 pounds for a period of ten minutes will not kill all spores of *B. botulinus.*

There is apparently some variation in resistance to heat between spores of different cultures of the same strain. Strains I, III, IV and VI seem to be less resistant sometimes than at other times. The age of the cultures used, however, varied a good deal, because spores form more quickly in some cultures than in others. Strains VII, VIII, IX and X give more nearly uniform results. Strains VIII, IX and X, which are the most recently isolated strains, are the most highly resistant to heat.

CONCLUSIONS

1. Free spores of *B. botulinus,* grown in either broth or brain cultures, are highly resistant to heat.

2. Spores grown in brain cultures are more resistant than spores grown in broth cultures.

3. Exposure of the spores to a temperature of 100 C. or more inhibits the development of the spores of *B. botulinus* so that the incubation period is very much increased.

4. The method of canning by boiling the fruit or vegetables in an open kettle and sealing in clean jars cannot be relied on to sterilize material that is contaminated with spores of the more resistant strains of *B. botulinus,* since spores of *B. botulinus* will survive in boiling liquid for three and one-half hours; and in the foam that gathers on the side of the kettle they may live for a much longer period.

5. The sterilizing processes of the cold pack (one period) method are not sufficient to kill spores of *B. botulinus.* Blanching in boiling water for five minutes is effective as a cleansing agent, but it does not materially injure spores of resistant strains of *B. botulinus.* One period of heating in boiling water for five hours or less will not sterilize the contents of jars if they are contaminated with the more resistant spores of *B. botulinus.*

6. Fractional sterilization on three successive days is of doubtful value because, after exposure to a temperature of 100 C. for from fifteen to sixty minutes, the germination of the spores is retarded so that they do not develop before the third sterilization period.

7. Pressure canning is the only method of sterilization that at present can be considered safe. But a pressure of 5, 10 or 15 pounds for ten minutes will not kill the more resistant spores of *B. botulinus.* Therefore a comparatively long sterilization period must be used.

8. With our present knowledge, the best way to guard against spoilage of canned goods due to *B. botulinus* is to prevent spores of this organism from entering the jars. The source of contamination is not at present known.[3] It is quite certain that the organism is not present under the skin of perfectly sound fruit and vegetables that are not overripe. Therefore, fruit and vegetables of this sort should be used. Bruised and partially spoiled material, if it is fit to use at all, should be consumed at once and not stored for future use. The fruit and vegetables should be thoroughly cleaned before they are peeled or cut in order that no foreign matter may be crushed into the pulp where it would be protected. It is possible that the spores of *B. botulinus* get into the jars from some source in the kitchen. For this reason it is essential that the hands and all utensils be made as clean as possible and that flies be eliminated. The use of sound fruit and clean methods of handling are the most important factors in canning, so far as *B. botulinus* is concerned, because the sterilization processes in common use will not kill all the spores.

9. It is important that housewives be warned of the danger of *B. botulinus* spoilage so that they may examine every jar carefully when it is opened for table use. The contents of the jar must not be tasted to "see if it is spoiled." The smallest taste will be fatal if the toxin is strong. There are three signs of spoilage from *B. botulinus,* any one of which is sufficient to condemn the jar. These are:

(*a*) Gas bubbles in the jars, the tops of the jars blown, and a squirt of liquid as the top is unscrewed.

(*b*) An odor somewhat resembling rancid cheese.

(*c*) A mushy or disintegrated appearance of the solid parts of the contents of the jars.

10. The toxin that *B. botulinus* produces after several weeks or months growth in a sealed jar may be entirely destroyed by boiling for five minutes, although the spores of *B. botulinus* are not killed by this treatment. It is the toxin and not the spores that produces illness, for the bacilli do not produce toxin when taken into the body. Therefore, any canned goods that are in the least suspicious should be emptied into a kettle and boiled for five minutes. They can then be eaten without danger.

11. Since *B. botulinus* produces toxin only in material that has been sealed in an air-tight container for a week or more, and since it produces no toxin in the human body, there is no danger of botulism from uncooked fruit or vegetables or from those freshly cooked.

---

[3] I am collecting material from places where cases of botulism occurred during the past winter in an effort to secure data as to the source of the contamination.

The Lacteal Goddess.—If civilized peoples were to lapse into the worship of animals, the cow would certainly be their chosen goddess. What a fountain of blessing is the cow! She is the mother of beef, the source of butter, the original cause of cheese, to say nothing of shoehorns, hair combs and upper leathers. A gentle, amiable, ever-yielding creature, who has no joy in her family affairs that she does not share with man. We rob her of her children, that we may rob her thereafter of her milk; and we only care for her when the robbery may be perpetrated.—Charles Dickens.

OUTBREAK OF MENINGITIS AT NORFOLK, VA.*

L. T. ROYSTER, M.D.
AND
W. P. McDOWELL, M.D.
NORFOLK, VA.

The conditions which influence the spread of contagious diseases are so numerous that it is impracticable to enumerate them. There are certain important ones, however, which a study of the recorded epidemics of cerebrospinal meningitis has shown to be not only potent but almost always coexistent. These are the bringing together of large numbers of people from widely separated areas, overcrowding, and unusually rigorous weather. Last winter these conditions existed to an exaggerated extent in Norfolk. The government activities in this locality incident to the war brought to our immediate vicinity about 50,000 additional people from every state of the Union, who are engaged in all of the pursuits necessary to building and construction on a large scale. Besides these there also came large numbers of officers and enlisted men of the Army and Navy with their families. This increased our population from about 100,000 to 150,000 in a little more than six months. The problem of housing this number was serious and resulted in uncomfortable crowding. In addition, we suffered the most prolonged season of severe weather that has visited this community for forty years.

GEOGRAPHY OF THE CITY

The city and suburbs comprising the territory under consideration occupy approximately 20 square miles. One large portion (Berkley and South Norfolk) is separated from the city proper by a branch of the Elizabeth River. In this section is located St. Helena, the naval training station. Six and one-half miles to the northwest of the city is the new Hampton Roads naval base, while between this point and the city is the new Bush Bluff Army base. Across the river to the south lies the city of Portsmouth, where are situated the Naval Hospital, the receiving hospital for the Atlantic fleet, and the Norfolk Navy Yard.

STATISTICS

During the period from January 1 to May 15, 1918, there occurred in the city proper, and immediately contiguous suburbs, forty cases of cerebrospinal meningitis. The epidemiology of this outbreak is of sufficient interest to justify an analysis. The wide distribution of the cases is shown on the map. Grouping is conspicuously absent. Twenty-two of the forty patients were male and eighteen female; thirty-one were white and nine colored; nineteen were over 15 years of age and twenty-one under; twenty-two, or 55 per cent., died and eighteen, or 45 per cent., recovered.

Twenty-one patients were treated in hospitals and nineteen at home. Of the twenty-one treated in hospitals, eighteen were treated at the City Detention Hospital, one at the Naval Base Hospital and two at St. Vincent's Hospital. Of the eighteen treated at the City Detention Hospital, ten recovered.

Several cases occurred after this report was closed, all of which ended in recovery. This would alter the death rate materially.

CLINICAL FEATURES

The severity of the cases varied from mild to fulminant. Death often occurred in the latter in a few hours after the onset. As would be supposed, the predominant symptoms and those occurring with greatest uniformity were headache, vomiting and retraction. The type of headache as described by those old enough to express their symptoms was of the vertex, frontal or occipital, and while the frontal type prevailed, there were several cases in which the pain was described as distinctly bitemporal (ventricles). Vomiting was a common symptom and was projectile, rarely accompanied by any nausea. Stiffness of the neck with more or less retraction was present in every case. A number suffered from pains in the back and limbs, so pronounced in some instances that a diagnosis of grip was made. Fever was uniformly present, though charts were not kept in a sufficient number of cases to enable us to trace a typical curve.

Convulsions occurred in nine cases, in five of which the patients died. Only two adults had convulsions. Maniacal delirium was present in nine cases, in five of which the patients died. Rash, either petechial or purpuric, was observed in fourteen cases, in ten of which the patients died. In several cases described as mild, the patients developed basilar conditions and died, while in several other cases described as severe or violent, the patients recovered promptly. In the fulminant cases, the early use of serum did not appear to influence the course or termination. Intravenous injections of serum were not used except in Case 25, in which the patient was treated at the Naval Base Hospital.

The reflexes usually described as present in the various types of meningitis were exceedingly variable in their appearance. Not one sign, with the exception of retraction of the neck, was constant enough in the early stages to be of diagnostic value. Most of the patients had one or more of the signs or reflexes present at some time during the course of the disease, most of them appearing or disappearing between daily examinations. In all cases there was a definite facies, which was apparent to the practiced observer on entering the room. This consisted in a peculiar fixed stare (very slight in some cases), slight stiffness of the neck and dilated pupils. To one accustomed to seeing this form of meningitis, this facies is almost pathognomonic.

LABORATORY DIAGNOSIS

Lumbar puncture revealed *Diplococcus intracellularis* in thirty-six cases. In three cases the diagnosis was clinical only (no lumbar puncture being performed), while in one case the spinal fluid was negative, but the organisms were found in a blood smear in abundance (Case 32[1]). In two other cases also blood smears showed organisms. These demonstrations occurred early in the course of the disease, which points strongly to the disease being a bacteremia before it became localized in the membranes of the brain and cord. One case showed a mixed infection of *Diplococcus intracellularis* and *Streptococcus mucosus* (Case 2).

---

* Owing to lack of space, this article is abbreviated in The Journal by the omission of case reports and a map showing the distribution of cases. The complete article appears in the reprints, a copy of which may be obtained on application to the authors.

[1] This case will be reported in full separately by Dr. D. P. West of Norfolk, Va., the attending physician.

TREATMENT

In every case treated with serum, commercial stock serum was used. The intraspinal method alone was employed. We regret that intravenous injections also were not given in several of the violent cases. In thirty-three cases in which serum was given, the average number of injections was five. One patient refused treatment and recovered. Another received one injection, refused further treatment and recovered. The average dose administered to adults was 30 c.c.; that to children, 15 c.c. No attempt was made to inject as much serum as the fluid removed (Sophian).

Five died without treatment, one of these because of the fulminant nature of the case, the others because of late diagnosis. One died of anaphylactic shock, five days intervening between the last two injections (Case 28). One died of intracranial pressure (Case 2). Three developed flaccid paralysis of the neck muscles while under treatment, one of whom recovered. One developed hemiplegia and recovered without permanent paralysis. So far as is known, of the patients that recovered, not one has been left with a stigma.

As to the frequency of doses, we have been guided by several factors, to wit: (1) by the improvement of symptoms; (2) by the turbidity of the fluid withdrawn (gradually clearing after first increasing cloudiness following the initial dose of serum); (3) by the bacteriology (the organisms first becoming entirely intracellular and finally disappearing), and (4) by the cytology (the cells first being polymorphonuclear, then mononuclear, and finally diminishing in number).

EPIDEMIOLOGY

The principal interest in this outbreak centered around the epidemiology. Attention has been called to the proximity of the various government activities to the city. Practically all of the civilian employees of the government live in the residential area of the two cities of Norfolk and Portsmouth. A description of this outbreak has to do only with what is geographically Norfolk; but the same conditions exist in Portsmouth. There are few residences in this section that now have no government employees lodging in them.

During the period from May 21, 1917, to June 1, 1918, the report of the Naval Hospital shows the admissions of cerebrospinal fever patients to be 131. This included admissions from St. Helena, the naval operating base, marine barracks, ships and stations, and also those cases developing in the hospital. The

FINDINGS IN FORTY CASES OF MENINGITIS

Case	Race	Sex	Age	Date of First Symptom	Symptoms	Date of First Puncture	Bacteriology of Spinal Fluid	Number of Treatments	Average Serum Injected, C.c.	Result	Presumed Source	Rash	Type
1	W	F	22	Jan. 4	Violent frontal headache and vomiting; rigidity of neck and retraction; maniacal delirium; petechial eruption	Jan. 6	Positive	5	30	Died Jan. 10	Was visited one week previous by fiancé from Camp Jackson, where meningitis was *prevalent*; reports showed him to be negative	Petechial	Violent

number of carriers is not stated. From January 1 to May 1, twenty-nine patients were cared for at the hospital at the Hampton Roads naval operating base, and 300 carriers were isolated. Men from all these stations come to the city and mingle freely with the population.

At the beginning of the outbreak, the laboratory of the Norfolk City Board of Health was not in a position to do the nose and throat culture work, the bacteriologist having recently been drafted. Later on the United States Public Health Service sent Dr. George Lake to assist in this work. At first, culture medium was hard to secure, and so even this work was imperfectly done for a time. Nevertheless, a large number of cultures were made in the houses where cases occurred, with varying results. A number of positive cultures were obtained, but a large number of those from persons suspected of having carried the disease were negative. The facts in the case will be stated, however, for what they are worth. They are highly suggestive. The accompanying table suggests the presumed source better than we can describe it. Of course, nothing absolutely conclusive can be deduced from this study, except in cases in which positive cultures were secured; yet, under the circumstances, we are forced to the conclusion that from all these various government activities there were many carriers that were never detected.

In twenty-six cases there was an apparently definite connection with either the naval base or the navy yard. In one instance the patient's mother was a waitress in a restaurant patronized largely by enlisted men. In one case the patient attended a reception and came in contact with Navy men. In the last instance the connection was very indirect but suggestive. Members of the patient's family danced with enlisted men at a reception. No cultures were made in this case.

It is quite apparent that this outbreak originated from without. There were no centers of infection in the city. With the single exception of mother and child, there was no connection whatever between the patients, none of them even knowing each other.

CLINICAL OBSERVATIONS

1. We treated only the patients under 15 years of age, but observed most of the others.

2. Intensive treatment should be conducted early.

3. Since the disease probably starts as a bacteremia, we think it advisable, at least in the early stages, to use serum intravenously as well as intraspinally.

4. Patients that are not well clinically after seven days' treatment rarely recover ultimately.
5. It is rarely necessary to give as much serum in the spine as the fluid withdrawn, 30 c.c. being a good average adult dose, and 15 c.c. a good child's dose.
6. Prolonged serum treatment frequently keeps the temperature raised without doing good.

REPORT OF CASES

Case 1.—*History.*—D. C., white woman, aged 22, was taken sick in the evening of January 4 with violent frontal headache and vomiting, followed within twenty-four hours by maniacal delirium, rigidity of the neck, marked retraction and diffused petechial rash. Lumbar puncture was done January 6; the fluid was cloudy and positive for meningococci. Treatment was begun at once, and she was given a daily dose of 30 c.c. of antimeningococcus serum on five consecutive days. There was no improvement, and death occurred, January 10, without the patient having regained consciousness.

Source.—The patient had been visited five days previous to the onset of illness by her fiancé, a young soldier from Camp Jackson, where there had been a number of cases of meningitis. Culture from the throat of this soldier was negative.

Case 2.—*History.*—Baby C., white boy, aged 4 months, was convalescing from bronchopneumonia of several weeks' duration, when, Janary 11, the attending physician detected stiffness of the neck. The child was seen in consultation at 8 p. m., January 13, at which time there was a marked degree of spasticity. Lumbar puncture was done immediately; 15 c.c. of slightly cloudy fluid were removed, and 6 c.c. of antimeningococcus serum administered. Examination of the fluid revealed a mixed infection of meningococci and *Streptococcus mucosus.*

On the morning of January 14, the patient seemed better. A second puncture was done, but not more than 2 c.c. of turbid fluid were obtained. On account of the urgency of the case, and in spite of the small amount of fluid withdrawn, the consultant (one of the authors) decided that more serum was indicated. At this time some difficulty was experienced in getting more than 2 c.c. of serum to flow into the canal by gravity, and only with the aid of slight pressure, by means of a rubber bulb, was it possible to introduce more than 4 c.c. The patient did well for ten minutes after the administration of the serum; he then went into a state of collapse suddenly and became cyanotic, with labored respiration. An immediate attempt was made to relieve the intracranial pressure, but death occurred before this was successful.

Source.—We were unable to trace any source of infection. Cultures from the nose and throat of all contacts were negative.

Case 8.—*History.*—L. M., colored girl, aged 15 years, was taken sick, January 22, with headache, backache, fever and restlessness. These symptoms continued, and on January 26 there was a marked degree of opisthotonos. Lumbar puncture was done on this date and 60 c.c. of slightly turbid fluid, under increased pressure, were removed. The fluid was positive for meningococci. Thirty c.c. of antimeningococcus serum were administered. There was no improvement, death occurring, January 29.

Source.—Two men living in the same house worked at the Army base. Cultures from the noses and throats of seven contacts were negative.

Case 9.—*History.*—M. S., white man, aged 56, was taken ill, January 26, with severe headache, vomiting and stiffness of the neck. He was seen by his physician a few hours later, at which time there was marked apathy, amounting to stupor. Lumbar puncture was done immediately; 30 c.c. of antimeningococcus serum were administered, and this amount was repeated daily for six days. Improvement was noticed after the first day, and the patient was discharged cured.

Source.—The patient was a rent collector and came in intimate contact with a large number of government employees in this community. Cultures from the nose and throat of five contacts were negative.

Case 12.—*History.*—E. B., white boy, aged 4½ years, was taken sick, January 25, one week following an attack of German measles, with fever, headache, vomiting and delirium. He was seen in consultation on the fifth day of illness, at which time he was semicomatose, with muttering delirium, from which he could be only partially aroused. There was stiffness of the neck with a marked degree of retraction. Kernig's and Babinski's signs were present, and there was a diffused petechial rash. Lumbar puncture was performed at once, and 40 c.c. of cloudy fluid, under pressure, were withdrawn. Fifteen c.c. of antimeningococcus serum were administered. Examination of the fluid was positive for meningococci.

The patient was removed to the City Detention Hospital and, ten hours following the first dose, he was given 15 c.c. of serum. After this, 15 c.c. of serum were administered daily for four consecutive days. Improvement was noticed after the second dose of serum, the fever declined, and the mental condition cleared up; but a few days later the patient developed a hemiplegia. This, however, was only transient, recovery was complete, and he was able to leave the hospital at the end of two weeks.

Source.—The boy's father and a boarder in the house worked at the naval base. Cultures from the noses and throats of five contacts were negative.

Case 13.—*History.*—N. J., white girl, aged 2 years, was taken sick, January 28, with fever and cough. By the next day she had developed stiffness of the neck with marked degree of retraction. She was seen in consultation at 9 p. m. of the second day. Lumbar puncture was done and 40 c.c. of clear fluid, under pressure, were withdrawn. In view of the marked rigidity and in spite of the clear fluid withdrawn, 15 c.c. of antimeningococcus serum were immediately given. A cell count of the fluid was not made, but bacteriologically it was found negative.

On the morning of the 30th another lumbar puncture was done, 30 c.c. of slightly cloudy fluid were withdrawn, and 15 c.c. of serum were administered. Examination of this fluid was positive for meningococci. The patient was given 15 c.c. of serum daily for six consecutive days. Improvement was noticed after the second dose, and recovery was complete.

Source.—The child's father was employed in the Navy yard. Cultures from the noses and throats of five contacts were negative.

Case 23.—*History.*—E. M., colored girl, aged 13 years, awoke on the morning of March 1 complaining of headache and slight fever. During the day she vomited several times. She was seen by her physician at 8:30 p. m., at which time there was stiffness of the neck and retraction. Spinal puncture was done immediately and 25 c.c. of cloudy fluid were removed. Examination of the fluid revealed many gram-negative diplococci. The patient was given 15 c.c. of antimeningococcus serum on two consecutive days. The disease ran a very mild course, the symptoms all cleared up after the first dose of serum, and the patient was discharged cured after one week.

Source.—Her father was employed at the Navy base. Cultures were all negative.

Case 24.—*History.*—R. D., colored man, aged 21, complained, February 28, of general malaise and headache, but he did not stop work. During the night the symptoms became progressively worse, and by the next morning, March 1, he was quite delirious. When seen by his physician, his neck was stiff, and there was a marked degree of retraction. Spinal puncture was done immediately, 50 c.c. of slightly cloudy fluid were removed under marked pressure, and 30 c.c. of serum were given. Smears made from the spinal fluid showed many gram-negative diplococci. The patient was given 30 c.c. of antimeningococcus serum daily for nine consecutive days. *Improvement* was noticed after the first dose, delirium and the mental condition clearing up within a few hours. The case ran a moderate course, and recovery was complete.

Source.—The patient was employed at the naval base, and the day before the onset of the illness he had been in conversation with a convalescent meningitis patient. Cultures from four contacts were negative.

CASE 27.—*History*.—Mrs. M., white, aged 46, awoke on the morning of January 6 complaining of headache, vomiting and myalgia. A physician diagnosed grip. These symptoms became progressively worse, and by the next day there was marked elevation of the temperature, delirium and a diffused petechial rash.

On the morning of January 8, the patient appeared very much better; the temperature was normal, the myalgia was relieved and the mental condition was clear. At 2 p. m. her husband found her semiconscious, delirious and suffering with intense frontal headache and blindness. There was opisthotonos with stiff neck, positive Kernig's sign and increased reflexes. Spinal puncture was done a few hours later. Thirty c.c. of cloudy fluid were removed which was positive for meningococci. The patient was given six intraspinal doses, averaging 30 c.c., of antimeningococcus serum. There was no improvement in the symptoms, death occurring, January 11.

Source.—The patient attended a wedding reception a few days prior to the onset of her illness, at which there was also present naval officers and enlisted men. All cultures taken from contacts were negative.

CASE 33.—*History*.—L. J., white boy, aged 6 years, was perfectly well until May 17, when he was taken suddenly ill with fever, vomiting and indefinite abdominal pains. May 18, he was quite apathetic. There was a marked degree of neck stiffness with retraction, positive Kernig's sign and increased reflexes. Spinal puncture on that date gave 30 c.c. of turbid fluid, under increased pressure. Examination of the fluid was positive for meningococci. The patient was admitted to the City Detention Hospital, where he was given 15 c.c. of antimeningococcus serum daily for five consecutive days. Improvement was noted after the first dose, and recovery was complete.

Source.—The patient was in intimate contact daily with a boarder in the same house who worked at the naval base.

CASE 40.—*History*.—T. I., white boy, aged 8 months, was taken sick, April 6, with slight fever, strabismus and muscular twitching. These symptoms continued, and on April 9 there was stiffness of the neck with retraction and diffused purpuric rash. Spinal puncture on this date gave 20 c.c. of very cloudy fluid, positive for meningococci. Fifteen c.c. of antimeningococcus serum were administered, but there was no improvement in the symptoms and death occurred in a few hours.

Source.—A few days previous to the onset, members of the family had attended a dance at which there were present a number of enlisted men from the Navy. No cultures were made.

We Should Live Up to Our Scientific Possibilities.—In short, Germany's scientific and industrial prestige was due chiefly to a better mobilization of forces; freer publication, better opportunities for research, to ideas and talent imported from other countries and plenty of push and pride in achievement. What we need in America is a better mobilization all along the line. We possess plenty of talent, as a rule not well directed nor given much encouragement. We have plenty of universities and industrial research laboratories of the highest grade, operating as uncoordinated individual units with very little team work to achieve large ends. We have many strong scientific and technical organizations, each holding regular meetings and supporting one or more journals. These organizations, like our universities, are strongly individualistic and exhibit very little team work or cooperation to achieve broad purposes. Science is only just beginning to be popular in our schools and in the public press; we need to advertise and popularize not only scientific and technical work, but especially deep, broad fundamental principles in every line of effort. Finally and most important of all, we need vastly increased effort in living up to our possibilities. In habitual effort the Teutons excelled us by at least 30 per cent. and at least equalized their deficiency in originality. We might easily double our stress of achievement without detriment to ourselves.—Dr. P. G. Nutting, *Science*.

FAVUS HERPETICUS, OR MOUSE FAVUS

POSSIBILITY OF PRODUCTION OF FAVUS IN MAN FROM AUSTRALIAN WHEAT [*]

R. E. BUCHANAN, PH.D.
Special Bacteriologist, Hygienic Laboratory, U. S. Public Health Service
WASHINGTON, D. C.

Immense stores of wheat have accumulated in certain districts in Australia for several years past because of the lack of shipping to carry it to the foreign markets. This wheat is placed in sacks and stored in great piles. The presence of these quantities of readily available food led to such rapid multiplication of mice, particularly field mice, that the control of these rodents and the saving of the wheat threatened to become a serious problem. The mice, however, were attacked by a virulent skin disease, which reduced their numbers rapidly. The damage already done to sacks and wheat necessitated the rebagging and shifting of a large portion of the grain. Men employed in this work and women engaged in mending gnawed and torn bags were in many cases attacked by a skin infection, apparently of murine origin. Accounts of this disease both in mice and in man have appeared within the last year by the Australian observers Paul[1] and Lawrence.[2] The latter diagnosed the disease in man as favus herpeticus caused by the dermatophyte *Achorion quinckeanum*, the parasite of mouse favus.

In spite of the shortage of shipping, the United States has been importing considerable quantities of Australian wheat. The question arises, Is there danger that men engaged in the handling and milling of the wheat may become infected with this skin disease? In an attempt to answer this query certain studies have been made at the Hygienic Laboratory of samples of wheat and of mouse skins collected in Australia by agents of the U. S. Department of Agriculture. Since there does not appear to be any general discussion of the geographic distribution of the disease, and only a few scattering notes on the disease published in English, a review of the literature of the subject has been undertaken.

DISTRIBUTION OF THE DISEASE: HISTORICAL

The first published note on favus in the mouse is that of Bennett[3] in England in 1850. In a footnote to a lecture on human favus, he records having seen a case of favus "on the face of a common house mouse, in which animal the same cryptogamic vegetations were to be detected as in man." According to Bazin,[4] favus in a trapped mouse was also reported by Draper[5] in New York. The infection had apparently been transmitted from mice to a cat, and from this animal to two children. Gluge and d'Ukedem[6] in Belgium described a skin disease of the mouse which was probably favus.

Three records of mouse favus in Germany were published in 1858. Friedrich[7] in Würzburg described a mouse brought to him by a student. The animal showed the whole region between the ears and snout covered by a yellowish white crust like a cap. The clinical picture was that of favus; this was verified by the microscopic findings. The parasite was believed to differ in some points of morphology from that of human favus. A somewhat similar account is that of Zander,[8] who noted that the disease might easily cause the death of an infected mouse. He also raised the question of identity between the fungus of human favus (*Achorion schoenleinii*) and that of mouse favus, which he termed *Achorion bennetti*. Since no description of the fungus is given, the latter name as applied to the mouse favus fungus has been overlooked, probably rightly, by subsequent writers. Schrader[9] reported an outbreak of favus among the mice in an old dwelling; mice caught practically all showed the characteristic favic lesions and excresences.

---

[*] Owing to lack of space, this article is abbreviated in THE JOURNAL by omission of the references to the literature. The complete article appears in the author's reprints.

The first evidence that favus can be transmitted experimentally from mouse to man was given by Pick,[10] in 1865. He succeeded in producing the disease in man by rubbing the skin with particles from the scutulum from a diseased mouse. He concluded that the diseases in man and the mouse are caused by the same parasite. Von Frauenfeld, in the same year, reported an epidermal growth on the head and ear of a house mouse, and identified the disease as favus. Tripier[11] observed cases of mouse favus in Lyons and transmitted the disease experimentally.

Mollière[12] found many cases of the disease mouse favus in Lyons. Simon[13] examined three mice caught in a workhouse in Hamburg. All of the animals showed well marked favic lesions. Later many other mice with favus were secured from the same place. He states that the disease frequently destroys the eyes and may be fatal to mice.

Apparently the first European instances of probable natural transmission of infection from mouse to man are those given by Anderson[14] in 1868 at Glasgow, Scotland. He described several instances of such transmission, among them a case of favus contracted by a young child probably from a trapped mouse, and afterward communicated to other members of the family. He noted that this disease in mice was reported as common in many homes in Glasgow.

Spontaneous transmission of favus from mouse to man were also recorded by Saint Cyr,[15] by Horand,[16] and by Rodet[17] in Lyons, and by Demons[18] at Bordeaux. Paton[19] recorded an extensive outbreak of "ringworm" among soldiers in barracks in England. A cat was found to be seriously affected with favus, and later large numbers of infected mice were observed. He states that the inhabitants of the country about were quite familiar with the disease, finding it "especially fatal to mice, common in cats and children, and occasionally affecting adults." Still later, similar reports were made by Megnin[20] and by Raillet[21] in Paris. In several cases (Rodet, Horand, Demons) transmission to man is alleged.

Flügge[22] stated that favus in mice had frequently been observed in his laboratory (Göttingen), and that Nicolaier had there cultivated the fungus and proved the transmissibility of the disease from mouse to mouse. He concluded that the typical human favus and mouse favus showed certain microscopic differences. This is apparently the first record of the cultivation of the fungus.

Careful studies of the favus fungi in the modern sense were first made by Quincke.[23] This investigator differentiated by cultural and pathologic characters three types of favus fungi from the lesions in man. These he termed the alpha, beta and gamma strains. The beta and gamma types were shown later to be the fungus typical of human favus, *Achorion schoenleinii*. The alpha fungus is of particular interest because it was later shown to be the characteristic fungus of mouse favus. The organism was isolated from the neck lesion of a miller. In general appearance the lesion resembled herpes tonsurans, covering an area about the size of a dollar. Examination showed it to be a true favus with herpetic rings. The only source of infection that could be adduced was in the bags of meal that he frequently carried on his shoulder. Quincke was told that another workman at the mill had a similar lesion on the cheek, but he did not see the case. This author made a careful microscopic and cultural study of the fungus, and proved the possibility of transmitting the disease by means of pure cultures applied to the skin of man, mice and dogs. From the lesions so produced he again secured the organism in pure cultures. Later Quincke[24] isolated the same alpha fungus from a young girl at Kiel. In searching for the origin of the disease, he found that mice in the barn in which the girl was accustomed to play were infected with favus. Still later he isolated the mouse favus fungus from the lesions of two cats. He summarizes the differences, clinical and microscopic, between true human favus and mouse favus, and suggests that the diseases in man be termed, respectively, "favus vulgaris" and "favus herpeticus." Boer[25] in Berlin isolated the alpha fungus from mice, and transmitted the disease from mouse to mouse.

The name *Achorion quinckeanum* by which the fungus of mouse favus is now generally known was given to Quincke's alpha fungus by Zopf.[26]

During the next decade there was much discussion concerning the number of species of fungi capable of producing favus in man. Some authors maintained that only one species could be recognized; others described as many as nine. Into the details of this controversy it is not necessary to enter, only certain work being pertinent.

De Fortunet and Courmont[27] isolated a fungus from a vesiculous eruption of a hand. This was studied by Busquet,[28] who regarded it as the fungus of mouse favus and termed it *Achorion arloingi*. Later[29] he concluded that all favus is caused by the same fungus, but he believed that the primary agencies in the distribution of the disease were the rats and mice. He records in support of this contention a case of favus on the hand of a young woman who had removed some diseased mice from a trap. Other mice caught later in the same place were found by him to be infected with favus.

Frank,[30] in Hamburg, made a study of cultures secured from cases of human favus and two from mice. He found that there were distinct differences between the fungus usually found in human favus and that in the mouse. Král[31] noted that Frank's mouse favus was transmissible to man.

Sherwell,[32] in Brooklyn, concluded that a number of cases of human favus were contracted from the lower animals. He mentioned a family in which two contracted favus from a dog, which in turn was probably infected from rats and mice. Many of the latter infected with favus were seen. Apparently this is the second American ascription of human favus to rodents.

Neumann[33] stated that mouse favus is common in Lyons, frequently proving fatal to the animals infected.

Hutchins,[34] in Atlanta, Ga., recorded a case of favus of the scalp of a young negro child, the disease apparently being contracted from white rats.

A favus fungus differing somewhat in its characteristics from those previously reported was described by Waelsch,[35] who isolated it from two favus mice from Hamburg. According to Sabouraud,[36] it is probable that the fungus isolated by Ingianni[37] from a case of human favus in Italy was *Achorion quinckeanum*.

Plaut[38] concluded that there exists only one species of the favus fungus, but that by long growth on different species of animals distinct strains have been produced which show a considerable degree of constancy, but which may be transformed one into the other.

One of the best modern descriptions of the fungus of mouse favus is that of Bodin.[39] He isolated *Achorion quinckeanum* once from a mouse from Autun and four times from mice from Rennes. He concluded that natural infection of man from mice is comparatively rare, but that it does occur.

Adamson[40] has given excellent accounts of several cases of human infection with mouse favus in England. Plaut,[41] (1909) in summarizing the knowledge concerning mouse favus, accepts the differentiation of the mouse favus from the human type. He concludes that favus of the smooth skin in man is usually of murine origin. An illustration is given of the arm and breast of a woman infected accidentally from a mouse. In contrast to Bodin, who reported about eight cases of body favus to a hundred in man, Plaut states that in his clinic in Berlin there are more cases of body favus (mouse infection directly or indirectly) than of the head favus.

Chajes,[42] in Berlin, reported an isolation of the fungus of mouse favus from a hand. He concluded that this type of infection is much more common in man than is commonly thought, for the disease is apt to be atypical and to be classed as a herpes tonsurans. Tomaszewski[43] gave an excellent description of the differential characteristics of human and mouse favus.

Probably the most extensive of the treatises on favus published is that of Sabouraud.[36] From his large experience in France he concluded that while there are distinct types of favus fungi to be found in animals, proved instances of their transmission to man are very rare. In his own clinic he has never seen an isolation of the mouse favus fungus in more than 200 cases of human favus. Bloch[44] protested the conclusions of Sabouraud, stating that in his own experience in Basel the mouse favus fungus producing the body lesions in man was much more common than the typical head fungus of man. He rarely observed *Achorion schoenleinii* except in the Russian and Italian immigrants. He recognized clearly that there are three distinct fungi capable of producing favus in man, *Achorion schoenleinii, A. quinckeanum* and *A. gypseum*. Later[45] he described a fourth, *A. violaceum*, cultivated from four cases of human dermatomycosis. He was able to differentiate the organism by its clinical effects and by its biologic and cultural characters. Two of the cases occurred in a house in which mice having favic lesions were caught, the same fungus being cultivated from both mice and man.

Plaut[46] states that favus is common among the mice in Hamburg, and that each year he sees cases of the disease in man. DuBois,[47] in Geneva, records two isolations of mouse favus from man.

Of particular interest is the appearance within the last year of the two papers first mentioned, relating to mouse favus and its spread to man in Australia. There seems to be some question as to whether the organism isolated by Paul,[1] and named by him *Trichophyton rodens*, is the same as the fungus that causes mouse favus. The descriptions and illustrations of Lawrence,[2] on the other hand, leave little doubt that he is dealing with *Achorion quinckeanum*. According to Paul, the characteristic skin lesions occur mostly on the exposed parts of the hairy regions of the face, producing a multiple kerion. In the particular case described, two months had elapsed between the opportunity for infection and the development of the lesions. Lawrence believes that Paul was not dealing with a typical case. Fungi isolated by the latter author both from field mice and from man showed the cultural characteristics of the mouse favus fungus, and identical lesions were produced in mice and guinea-pigs inoculated with cultures from each source. The lesions in man show well developed scutula in some cases, and correspond accurately to the descriptions of the favus herpeticus of Quincke.

From this summary, it is evident that a distinct disease, mouse favus, exists commonly in Belgium, England, France, Germany, Italy, Scotland, Switzerland, probably other parts of Europe, Australia and probably more rarely in the United States. There is abundant evidence of the transmissibility of the disease from mouse to man, producing the favus herpeticus of the glabrous skin. It is apparent that the disease is of sufficient importance to warrant the careful study of the possibility of its importation into the United States with Australian wheat. Even though it should be imported, however, there would probably not be good reason for excluding the wheat, for the disease in man is usually not serious, and yields readily to treatment. It is much more amenable to treatment than the human favus of the scalp. In mice, however, the disease frequently, perhaps generally, proves fatal.

EXPERIMENTAL

Samples of Australian wheat from two sources were examined. One sample contained parts of the dried skins of two mice. The latter were so dried, dusty and adherent to the cotton in which they were wrapped that a satisfactory examination proved difficult. No typical favic scutula or crusts were present. Scrapings from the denuded areas showed fungus hyphae, but the material was too meager and in too poor condition to permit a reliable diagnosis. It is possible that the mice examined had been infected, but there was no microscopic proof. Many attempts were made to infect mice and guinea-pigs from these skins and from the wheat. All were without result. No fungus resembling that of favus was secured as the result of numerous culture attempts. If present originally, in the wheat samples or the mouse skins, the fungus probably had died as a result of the prolonged desiccation.

In view of these negative experimental results, the question may arise as to the possibility of spores or hyphae of the mouse favus surviving transportation. Data on the longevity of the fungi of this group are not abundant. Sabouraud states that the fungus of favus, at least as it exists in the scutula, remains viable for a considerable period. Sabrazès found that the spores in the scutulum were still alive after two years. Apparently they are more resistant than are those of other dermatophytes. It is not improbable, therefore, that under certain conditions there may be an occasional appearance of mouse favus or, better, of favus herpeticus, among those handling Australian wheat in the United States. The possibility of the spores being present in flour and causing infection in bakers is very remote. Careful studies of the thermal death point of the spores of this fungus apparently have not been made, but related to trichophytes have been shown to be readily destroyed by heat. It is not at all improbable, however, that some of the mill by-products used as animal feed may contain viable spores and infect mice, or possibly other animals or man occasionally.

CONCLUSIONS

1. There exists in many parts of Europe and in Australia, and probably in the United States and in other parts of the world a disease, mouse favus, the cause of a highly fatal infection among mice and not infrequently transmitted to man, producing a herpetiform favus of the smooth skin. The disease in man usually yields readily to treatment.
2. Samples of mouse skins and of wheat from Australia failed to show evidence of favus. That the disease is prevalent among the field mice that have attacked the Australian wheat stores seems to be established through the accounts of Paul and of Lawrence.
3. It is not improbable that cases of favus herpeticus may arise occasionally among men who handle the imported Australian wheat or in animals, particularly rodents, that feed on the grain or on certain of the mill by-products.
4. It is not probable that the danger from the disease is great enough, or the disease itself serious enough, to warrant interference with the importation of the wheat from Australia.

A CASE OF MULTIPLE CHANCRES OF THE PENIS

JAMES C. SARGENT, M.D.
MILWAUKEE

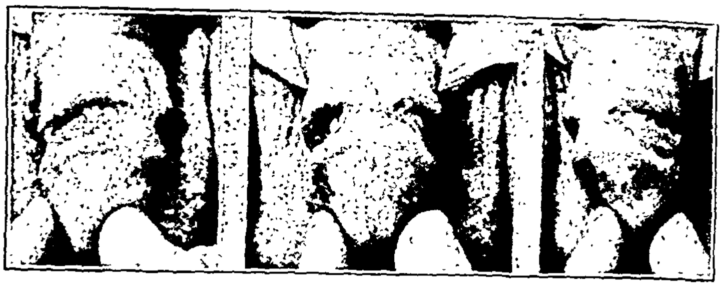
Referring to the primary lesion of syphilis, Osler[1] states that "in about one fourth of the cases it is multiple." Contrary to this opinion, a perusal of the literature of the past ten years reveals but one complete case report of multiple chancre. Zeisler[2] describes in detail the case of a young colored woman who presented two separate lesions situated on the lower lip, both of equal duration. Each presented the typical appearance of a chancre, and each was proved so to be by dark-field examination of the expressed secretion. The same author mentions recalling having seen a case of double chancre of the cheek.

Because of the paucity of reported cases of multiple chancre, I have deemed a case recently coming under my observation as being worthy of complete description. The case is of special interest not only because it presents two separate chancres but also because there was a difference of four weeks in the development of the two lesions.

REPORT OF CASE

History.—H. J., white man, single, aged 28, a drill dresser, (Marquette Dispensary No. 6855), admitted Oct. 28, 1918, had had a single small sore on the penis in 1913, which healed in several days with the application of some yellow powder. Neither rash, sore throat, falling hair, nor bubo followed. The patient admitted intercourse, August 10, and, with a different party, September 3, but at no time subsequently.

September 7, he noticed a small sore in the coronal sulcus on the right side of the penis. This sore continued to increase in size, but was not of sufficient size to warrant much concern until it had been present two weeks. October 5, four weeks after the appearance of the first sore, the patient noticed a separate sore developing in the coronal sulcus on the left side of the penis. In spite of repeated applications of mercuric oxid both sores had continued to increase in size. About October 20, the patient began noticing a soreness of the throat which had persisted. About October 25, the patient noticed a rash.



Multiple chancre of penis.

Physical Examination.—The entire pharyngeal wall was everywhere inflamed but not ulcerated. There was a faint but distinct macular rash, more prominent on the neck and chest but also seen on the face, back and extremities. There was a general lymphadenitis, not particularly marked, in each groin. In the coronal sulcus on each side of the penis was a large, typical hunterian chancre, ulcerated on the surface and situated on a hard, indurated base. The two chancres were completely separated by a centimeter of perfectly healthy tissue.

Laboratory Findings.—By carefully collecting a drop of serum expressed from the margin of either sore, Dr. Daniel Hopkinson succeeded in demonstrating the presence of *Spirochaeta pallida* in both lesions. The Wassermann test of the blood was found to be + + +. After the first injection of 0.4 gm. of arsphenamin there was a characteristic healing change noted in each sore.

COMMENT

That both lesions represent the same infection, one developing after four weeks' incubation and the other after eight weeks' incubation, seems altogether improbable. There remain but two other possibilities: The first, that the right chancre represents the original infection contracted four weeks before its appearance, and that after a second incubation period of four weeks, a transplanted chancre developed on the left; the second, which seems the more probable, that the right chancre was contracted August 10 and the left chancre September 3, each developing after four weeks' incubation.

Wells Building.

Hygiene.—Only unpractical people ignore hygiene. Hospitals, insane asylums, jails and poorhouses are monuments to our ignorance and conceit. We must know, we must understand, and we must practically apply our knowledge of hygiene; otherwise we perish.—*Monthly Bulletin*, Indiana State Board of Health.

TUBERCULOSIS OF THE STOMACH

WITH REPORT OF A CASE OF MULTIPLE MILIARY TUBERCLES

G. A. FRIEDMAN, M.D.
Clinical Professor of Medicine, New York Polyclinic Medical School and Hospital; Visiting Physician, Beth David Hospital; Gastro-Enterologist, Gouverneur Hospital
NEW YORK

Tuberculosis of the stomach is a rare condition. In a series of 2,501 gastric operations at the Mayo Clinic, tuberculosis was found only once.

From a recent paper of Broders[1] on this subject, with a complete bibliography up to 1917, it is evident that tuberculosis of the stomach had been described before the discovery of the tubercle bacillus of Koch in 1882.

According to Broders, gastric tuberculosis may be divided into six types: (1) ulcer, single or multiple; (2) miliary tubercle; (3) solitary tubercle; (4) pyloric stenosis; (5) tumor or nodule, single or multiple, and (6) lymphangitis.

The case reported here apparently belongs to Type 2.

REPORT OF CASE

History.—S. S., woman, aged 20, clerk, single, admitted to my service at the Beth David Hospital, Feb. 21, 1918, and discharged, March 26, 1918, complained chiefly on admission of pain in the epigastrium, pain in the precordial region, attacks of vomiting, headaches, loss of flesh, weakness and constipation. The father and two sisters had indigestion. There was no history of tuberculosis, carcinoma, diabetes or alcoholism. The patient had had scarlet fever, measles and diphtheria, and was anemic in early childhood. She began to menstruate at the age of 14. The menstrual periods occurred every five weeks. There was a moderate flow for four or five days. Pain in the lower abdomen was felt on the first and second day of the menstrual flow. The patient ate and slept regularly, chewed the food well, and drank one cup of tea and one cup of coffee daily. She drank no liquors. Her appetite was poor. She denied venereal *diseases.*

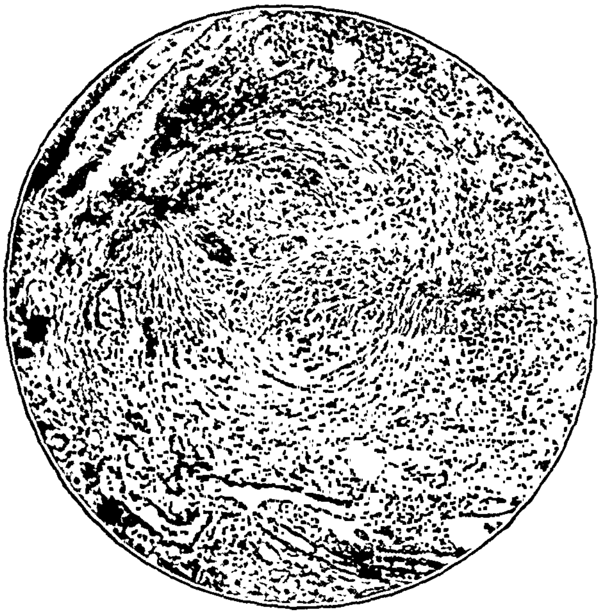

Fig. 1.—Section from tubercle, × 100.

Four months before, while visiting friends, the patient ate some roast meat and swallowed a large piece. On returning home she felt nauseated and after taking a purgative was somewhat relieved. One week later she began to feel a dull pain in the pit of the stomach which was relieved in from one half to one hour after taking food, only to begin again three hours later. The pain radiated to the left of the epigastric region.

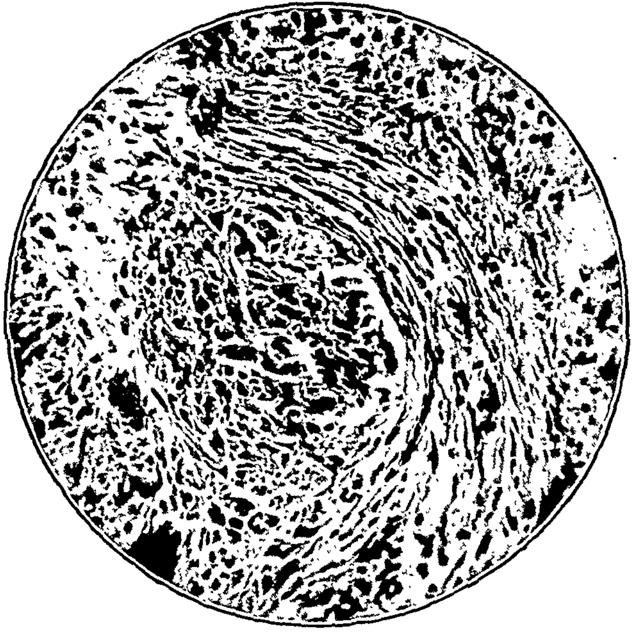

Fig. 2.—Section from tubercle; × 215.

The patient also experienced pain on bending forward, on breathing or laughing. For the last two weeks she had been awakened by pain about 2 a. m., and was relieved by turning on the right side. She vomited on several occasions during her illness. Occasionally she had headaches in the supraorbital region, without any relation to the partaking of food. The bowels moved only after the patient had taken liquid petrolatum. She had never noticed any blood in the stools, nor did the evacuations at any time have a tarry appearance.

Physical Examination.—The heart and lungs were normal. The patient had a high arched palate. There was slight prominence of the thyroid gland. A fairly marked rigidity was noticed in the upper abdomen, especially to the left side and exaggerated knee jerks.

Preoperative laboratory examinations revealed: Blood: hemoglobin, 85 per cent.; erythrocytes, 4,800,000; leukocytes, 12,000; polymorphonuclears, 59 per cent.; lymphocytes, 31 per cent. Urine: Albumin and sugar were negative, and indican not in excess. There were no casts. A few calcium oxylate crystals were noted. Gastric Analysis: After a test breakfast, 210 c.c. of contents were obtained. Free hydrochloric acid was 18, and total acidity 56. There was no blood. Roentgenoscopy revealed ulcer at the lesser curvature of the stomach with adhesions.

Operation and Result.—A median 5 inch upper abdominal incision was made by Dr. A. O. Wilensky, March 5, 1918. An area of the lesser curvature of the stomach about 2 inches long, extending to the anterior and posterior surface of the stomach for an equal distance was thickened and inflamed. There were numerous fresh fibrinous adhesions and large numbers of miliary tubercles thickly scattered over the inflamed area. The condition extended upward into the gastrohepatic omentum for about 1 inch. The gross diagnosis was tuberculosis. The remainder of the abdomen was explored, but no other focus of tuberculosis was found. The abdominal wall was sutured in layers and dry dressing applied.

MEDICAL COLL
LIBRARY

The pathologic report of section from one of the tubercles removed at the operation was: caseation of tubercle, giant cells and nuclei (Figs. 1 and 2).

Roentgenoscopy of the chest, March 16, 1918, revealed the usual amount of peribronchial thickening. There were no

Dr. Robert

suspicious areas. The von Pirquet test, March 21, 1918, was reported positive by Dr. Jersky.

The complement fixation test made independently by Drs. H. R. Miller and Jersky were reported as weakly positive.

The patient made a good recovery and was discharged, March 26, 1918, apparently well.

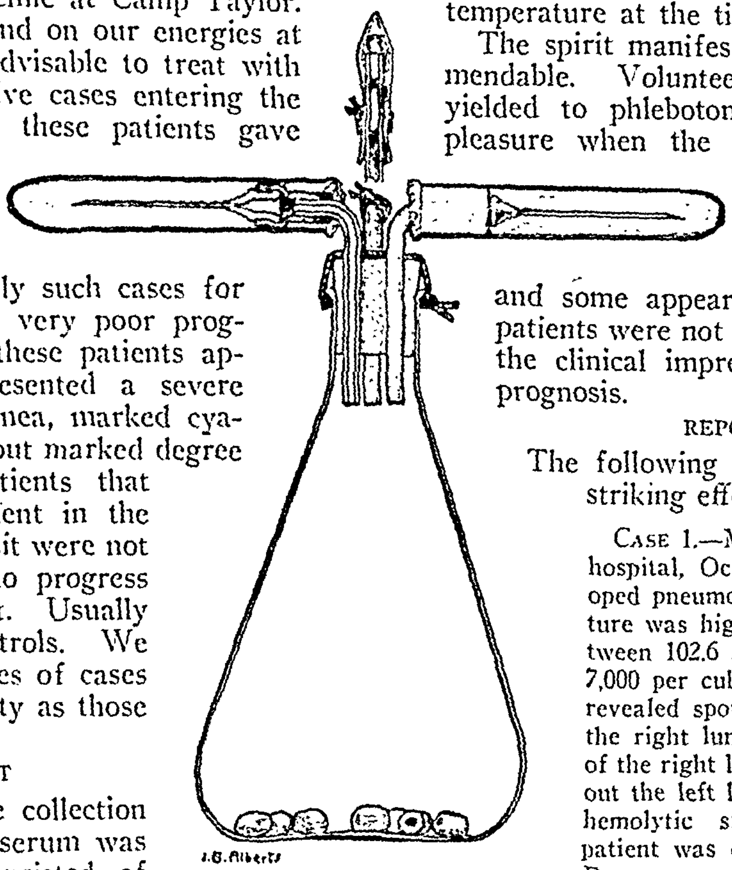
63 East Eighty-Fourth Street.

SERUM TREATMENT OF POSTINFLUENZAL BRONCHOPNEUMONIA *

MORRIS H. KAHN, M.D. (New York)
Lieutenant, M. C., U. S. Army
CAMP ZACHARY TAYLOR, LOUISVILLE, KY.

The use of serum from patients convalescing from postinfluenzal bronchopneumonia in the treatment of this disease was suggested by the author early during the appearance of the epidemic at Camp Taylor. As there was a great demand on our energies at the time, it did not seem advisable to treat with serum a series of consecutive cases entering the hospital, because many of these patients gave promise of recovering without it, and the treatment would have been superfluous.

We therefore selected only such cases for serum treatment as gave a very poor prognosis clinically. Some of these patients appeared moribund. All presented a severe toxemia with extreme dyspnea, marked cyanosis, fever, and a variable but marked degree of lung involvement. Patients that showed signs of improvement in the day or two preceding our visit were not treated, as they promised to progress favorably without treatment. Usually these were selected as controls. We thus used as controls a series of cases of the same type and severity as those we treated.



Apparatus for collection of serum.

SERUM TREATMENT

The method used for the collection and the preparation of the serum was simple. The apparatus consisted of 500 c.c. Erlenmeyer flasks fitted with rubber stoppers through which three L-shaped tubes led outward. To two of these a large-caliber needle was attached by means of a short piece of rubber tubing, and protected by a glass covering as shown in the illustration. The third piece of glass tubing was plugged with cotton and used as an exhaust for suction when the blood was being drawn.

The blood was taken under sterile precautions from the elbow veins, with a tourniquet around the arm. We collected from 300 to 400 c.c. from each donor. Two donors felt faint during the phlebotomy, but no other consequences were noted.

The blood was allowed to stand for from twelve to eighteen hours in the refrigerator. The serum was then decanted under sterile precautions and tested for complement fixation against syphilis. Serum showing a positive Wassermann reaction was discarded. It was deemed unnecessary to test hemolytic or hemagglutinative reactions between the bloods of donor and recipient, as the amounts were not sufficient to make these reactions in the circulation of consequence. The serums of two or three donors were mixed and about 100 c.c. were given intravenously at each injection. Most of the patients received two injections within twenty-four hours. A few received three injections and some, the apparently moribund patients, necessarily had only one injection. In some of the cases a preliminary phlebotomy of a small amount of blood was done. The details will be mentioned in the case reports.

Convalescent influenza patients and influenzal bronchopneumonia patients were used as donors. In the treatment of the last twenty cases of our series only bronchopneumonia convalescents were used. We chose preferably full-blooded large-built individuals in whom the disease had been severe. In most of these, less than one week had elapsed of normal temperature at the time of phlebotomy.

The spirit manifested by the donors was commendable. Volunteers responded heartily and yielded to phlebotomy with an avowed heroic pleasure when the purpose of the work was stated to them.

The patients were all in a very critical condition at the time of the injection, and some appeared moribund. The control patients were not treated because they all gave the clinical impression of a more favorable prognosis.

REPORT OF CASES

The following cases especially indicate the striking effects of the serum treatment:

Case 1.—Major A. D. C., admitted to the hospital, October 14, with influenza, developed pneumonia, October 21. The temperature was higher, October 22. It ranged between 102.6 and 99.4. The leukocytes were 7,000 per cubic millimeter. Roentgenoscopy revealed spot shadows in the upper lobe of the right lung, a shadow in the lower lobe of the right lung, and spot shadows throughout the left lung. The sputum showed nonhemolytic streptococci. October 25, the patient was extremely toxic and jaundiced. Dyspnea was marked, cyanosis was present, and the patient was dull mentally. At 4:30 p. m., 100 c.c. of serum were given after a preliminary phlebotomy of about 60 c.c. of blood. Within six hours there was much improvement. The following morning the dyspnea was much less, the cyanosis diminished and the patient more alert. The improvement was remarkable. October 26, at 5:30 p. m., another intravenous injection was made of 100 c.c. of serum after preliminary phlebotomy of 50 c.c. of blood. The temperature promptly reached normal, and recovery continued uneventful.

Case 2.—R. L. B. was admitted to the hospital, October 14. October 20, his left chest showed dulness and bronchial breathing below the level of the fourth rib; the right chest was slightly less involved. October 24, the patient appeared moribund. The white blood count was 7,900 per cubic millimeter. The temperature ranged about 102 F. There was extreme dyspnea, marked delirium, cyanosis and rapid, bounding pulse. The condition seemed hopeless, with beginning pulmonary edema and overwhelming toxemia. At 11 p. m., 90 c.c. of immune serum were given. The following morning the temperature was 99.4 F., and in the afternoon it fell to 98 F. The toxemia still persisted, though the improvement following the serum injection was surprising. October 26, at 11 a. m., with the patient still toxic, an additional 70 c.c. of serum were given. Recovery thereafter was progressive.

---

* From the Medical Service, Base Hospital, Camp Zachary Taylor, Ky.

Case 3.—H. L., admitted to the hospital, October 9, developed pneumonia soon after. The temperature varied between 102.4 and 104.6 F. Roentgenoscopy revealed spot shadows throughout the right lung. The sputum showed pneumococcus Type IV. October 25, the temperature was 102; there was evidence of marked toxemia; marked dyspnea and cyanosis, delirium and jaundice. At 11:30 a. m. an intravenous injection of 80 c.c. of serum was given. The patient's condition continued unchanged for three days, during which the toxemia increased, the jaundice was marked, and the fever continued. October 28, at 2 p. m., a second injection of 100 c.c. was given, and this was repeated at 10 a. m. the following day. The patient improved promptly, and recovery was uneventful.

Case 4.—C. C., admitted to the hospital with influenza, September 27, developed bronchopneumonia. Roentgenoscopy revealed shadows in the lower right lung and the middle portion of the left lung. The temperature varied between 102 and 103. October 22, the condition was very critical; the patient was semiconscious. His temperature was 102, with marked dyspnea and cyanosis. At 3:30 p. m., 100 c.c. of serum were injected intravenously. The following morning the temperature fell to 100.8 F. At 10 a. m., 100 c.c. of serum were again given. The patient still remained toxic and irrational. At 10 a. m., October 25, 100 c.c. of serum were again given. The patient's recovery seemed irrefutably prompted by the use of the convalescent serum.

Case 5.—W. M. S., aged 27, admitted to the hospital, September 30, developed bronchopneumonia later, and on October 22 appeared to be moribund. He was semiconscious, toxic, dyspneic and cyanosed, and meningeal involvement was suspected. At 9 p. m. on that day, 100 c.c. of serum were given intravenously. The patient seemed much improved the following morning, and his recovery was progressive after the one injection.

SUMMARY

1. Twenty-five patients with clinically grave prognosis, toxemia, extreme dyspnea and cyanosis and extensive lung involvement were treated with serum from convalescent influenzal bronchopneumonia patients.

2. The mortality, as determined from the final disposition of the patients in this series, was twelve, or 48 per cent.

3. Eighteen other patients with prognosis equally grave clinically were used as controls and treated like the others, but without the use of serum.

4. The mortality in this series was twelve, or 66.6 per cent.

5. The selection of the most severely ill patients was deemed more correct for judging the value of the immune serum than the selection of a series of consecutive patients, the larger number of whom would recover without the use of the serum.

6. From the relative percentage mortality in the two series as well as from the surprising beneficial effects of the serum in individual cases, we believe that serum from convalescent influenzal bronchopneumonia patients deserves further trial in the treatment of the disease.

7. It may perhaps act as a favorable antitoxic factor in the circulation to assist in the general reaction to the pathologic process.

8. It must be emphasized that the number of cases in this series does not warrant very positive conclusions.

The Alkaline Reserve in Shock.—In shocked men there is a reduction of the so-called "alkaline reserve" of the blood, that is, the amount of sodium bicarbonate present. This is due to the development of nonvolatile acids which unite with the sodium and drive off the carbon dioxid.—*Review of War Surgery and Medicine.*

PHYSICAL EXERCISES IN USE IN THE CARDIOVASCULAR SERVICE

GENERAL HOSPITAL NO. 9, LAKEWOOD, N. J.

BERTNARD SMITH, M.D. (Los Angeles)
Captain, M. C., U. S. Army
LAKEWOOD, N. J.

The exercises here reported were planned for the training of soldiers with "irritable heart," and they have been used for a sufficient length of time to prove their value in physical development and in estimating the fitness of the men for military service. Tests of muscular strength have shown that a large proportion of the men, sent to this hospital on account of the symptoms that characterize the "irritable heart of soldiers," are of poor muscular development. They give, also, a history of having lived, in civil life, at a physical level considerably below that at which their symptoms appear. In many instances the situation is complicated by the fact that for years their families and physicians have continually impressed on them the idea that they must "take it easy," and never "overexert," on the grounds that they were "not strong" or that they had a "weak heart." The main problem, in such cases, is to improve the general physical condition of the patients, and but little progress can be made in this direction until they begin to get some self-confidence, and realize that even if they do get tired, short of breath or have some pain in the chest, nothing serious is going to occur. This type of individual must be gradually taught that it is safe for him to venture beyond what he has previously considered the limit of his physical activity. With this in view, the exercises of the first and second grades are given in slow rhythm, and care is taken to avoid short, snappy commands. The only part here carried out with anything like

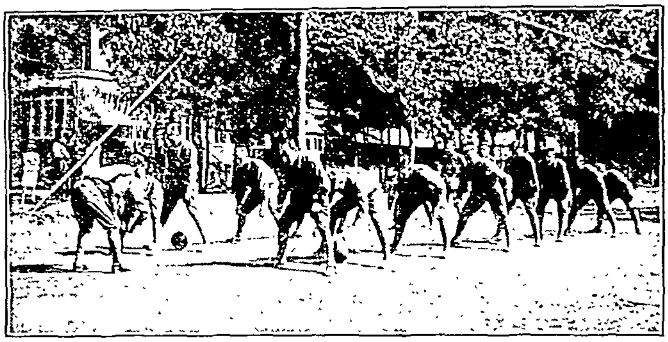


Fig. 1.—Stride ball relay, for advanced grades.

Fig. 2.—Push ball, for advanced grades.

military precision is stepping from the line to the position for the exercises. This is done promptly on the command.

One medical officer is present at each exercise period. He watches the men closely, noting any objective signs that may indicate overexertion, and recording any symptoms that may be voluntarily mentioned by the patient. No observations are made on the pulse rate or blood pressure, and everything possible is done to direct attention away from the heart and to focus it on the problem of general physical development. The medical officer is the only person having the right to grant excuses from the exercises, and he decides when the men are ready to advance in the grades. The usual length of stay in each grade is one week, but in some instances this must be prolonged. It is not uncommon for a patient to complain of subjective symptoms for the first day or two when beginning a new group of exercises, and to have the symptoms disappear when he is reassured as to their triviality and made to continue until he becomes accustomed to the work of the grade. The medical officer in charge of the physical training has a very important part in making the work a success. It is essential that the patients should have absolute confidence in his professional ability. He must be a good judge of men, and must be able to distinguish clearly between those who, lacking self-confidence, need to be encouraged, and those who are lazy or malingerers and need to be driven or disciplined. By informal talks with the men, either one at a time or in small groups, he can exert an influence that is of value in both discipline and development.

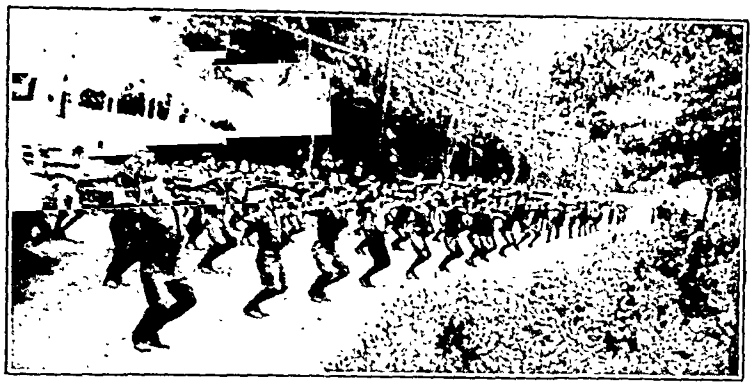

Fig. 3.—Combined cardiac class.

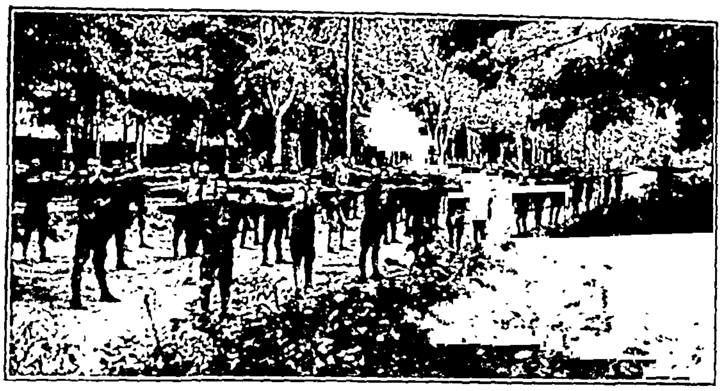

Fig. 4.—Cardiovascular patients in graded exercises.

It has been found in this hospital that the interest of the men in the exercises is greatly stimulated by checking up the degree of improvement with muscular strength tests. The method of Martin[1] is used. These tests enable the men to see for themselves the progressive improvement in their physical condition. It is also regarded as important that the exercises should be given by physical trainers who have had considerable experience and also understand thoroughly all the details as to the way in which the various exercises should be carried out.

INTERPRETATION OF THE COMMANDS

A few explanations of some of the commands used may be useful:

Arms forward: The arms straight, shoulder high and shoulder width apart, palms turned inward and shoulders back.

Arms forupward: Arms raised upward by passing through the arms forward position.

Arms sideward: Arms shoulder high, hands slightly behind a line drawn through the shoulders, palms downward.

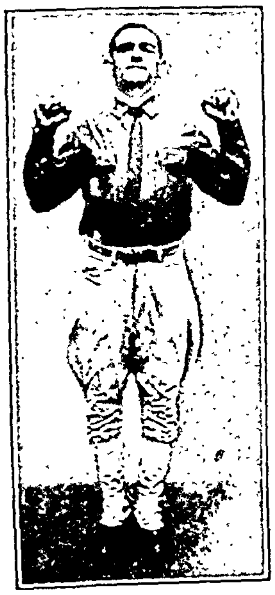

Fig. 5.—Grade I, Exercise 3.

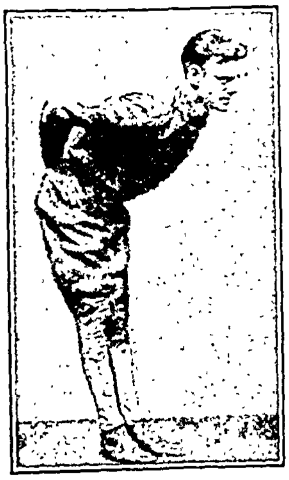

Fig. 6.—Grade I, Exercise 4.

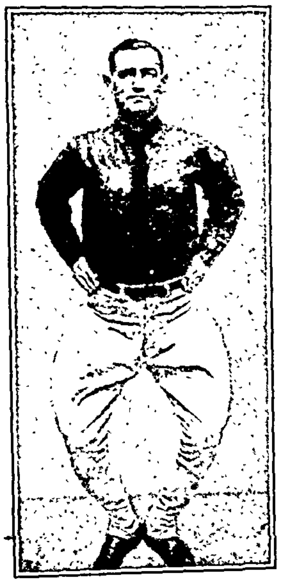

Fig. 7.—Grade II, Exercise 3.

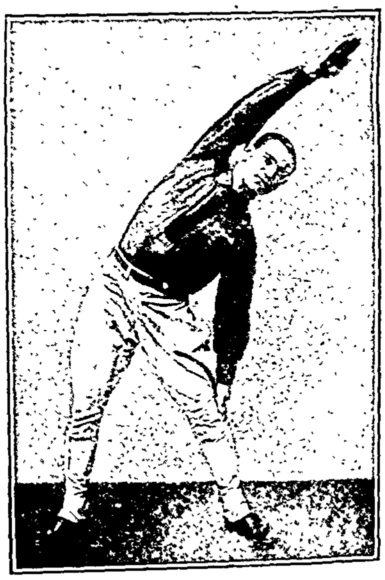

Fig. 8.—Grade II, Exercise 6.

Arms sideupward: Arms raised through arms sideward position, palms turned inward as the arms are raised upward above the shoulders.

Arms backward: Arms are raised over the head and backward as far as possible, with chest raised.

Hands on hips: Hands firmly on hips, thumbs to the rear, elbows and shoulders well back.

---

[1] Martin, E. G.: Am. J. Physiol. **46**: 67, 1918.

Arms bent for thrust: Arms bent, elbows close to sides, forearm verterical, hands clenched at side of shoulder, knuckles outward.

Arms bent for strike: Hands clenched over shoulders, knuckles to the rear, elbows shoulder high and well back.

Support lying frontways: Weight supported on hands and toes—the arms, trunk and legs straight.

Trunk bent forward: Back bent as much as possible, head up, knee straight. Head leads in return movement.

Trunk lowered one half forward: Back flat, head up, trunk carried midway between vertical and horizontal positions.

Trunk lowered forward: Back flat, trunk to horizontal, head up.

Trunk bent backward: Chest raised, head and neck lowered backward as a unit, chin in, knees straight. The bending is in the upper spine.

Trunk bent sideward: Body bent directly sideward, knees straight, feet flat on the floor.

Chest raised: The chin drawn in and the chest raised upward and forward.

Heels raised: Heels raised, ankles fully extended, weight on toes, heels slightly separated.

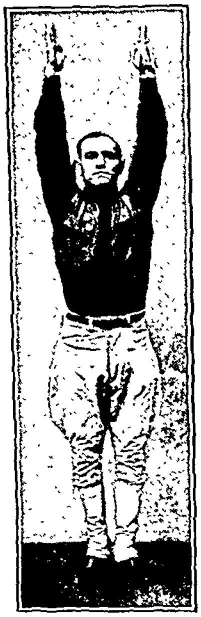

Fig. 9.—Grade III, Exercise 1.

Knees bent: Heels raised and slightly separated, knees bent outward, body erect, head up.

Leg raised: Body held erect, chest raised, leg raised as high as possible, knee and ankle extended.

Foot placed: Foot placed in given direction, toes touching floor, leg straight, weight on stationary foot. Feet about 18 inches apart.

Stride: Weight equally divided on both feet, feet flat on floor. Feet about 24 inches apart.

Side Step: In given direction. Weight transferred to stepping leg, heel of stationary foot raised. Distance about 24 inches.

Lunge: Leg raised and a step taken in given direction, knee of stepping leg bent, feet flat on floor, body erect. Distance about 24 inches.

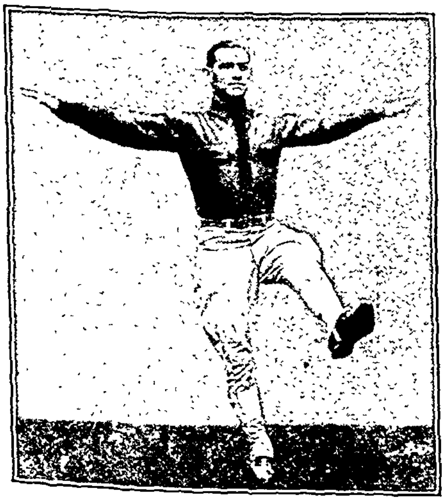

Fig. 12.—Grade IV, Exercise 3.

Feet closed: Inner edges of feet together, knees together.

Head lowered backward: Chin drawn in, head and neck lowered backward as a unit.

RHYTHM OF MOVEMENTS

Arm and leg movements are usually taken in fast rhythm.

Trunk and head movements are always taken in slow rhythm.

The balancing exercises are done on count or command. These exercises are the third in each of the various groups.

In compound exercises, the rhythm is that of the slowest movement.

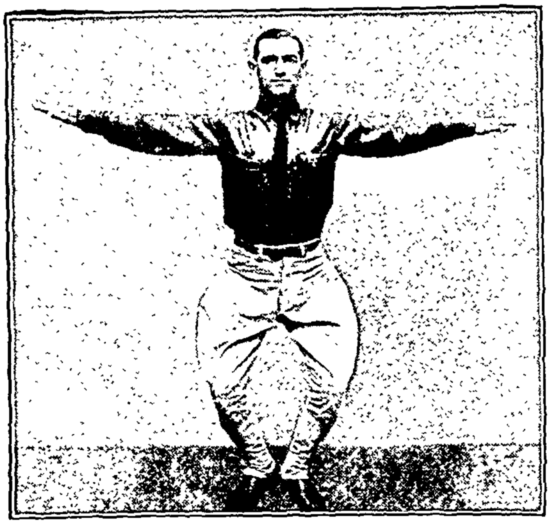

Fig. 10.—Grade III, Exercise 3.

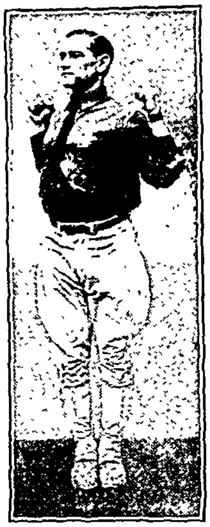

Fig. 11.—Grade III, Exercise 6.

EXERCISES

Grade I (fifteen minutes):

1. Raise arms sideupward—1. Return—2.
2. Arms bent for thrust: Straighten arms sideward and raise chest—1. Return—2.
3. Bend arms for thrust: Raise heels and chest—1. Return—2.
4. Hands on hips: Lower trunk one half forward and exhale—1. Return—2.
5. Bend arms for thrust—1. Straighten arms upward—2. Return—3,4.
6. Hands on hips: Bend trunk left—1. Return — 2. Right—3, 4.

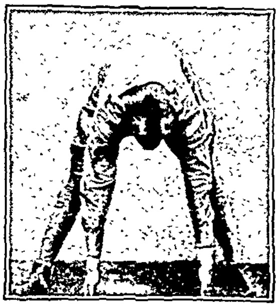

Fig. 13.—Grade IV, Exercise 4.

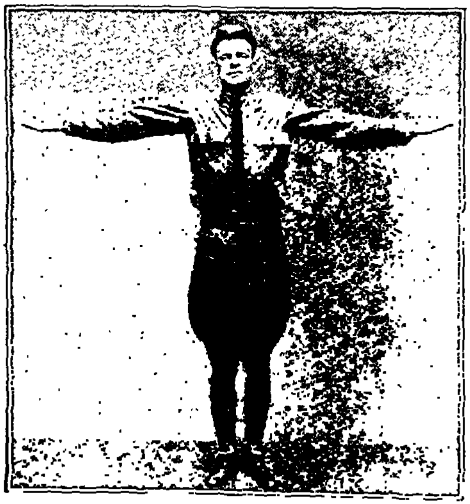

Fig. 14.—Grade IV, Exercise 8.

7. March in place (one minute).
8. Raise arms sideward and inhale. Lower and inhale.

Grade II (fifteen minutes):

1. Arms bent for thrust: Thrust arms forward—1. Return—2.
2. Raise heels and chest. Inhale—1. Return—2.
3. Bend knees one half deep—1. Return—2. (Hands on hips.)

4. Hands on hips: Raise chest and inhale—1. Lower trunk one half forward and exhale—2. Return—3, 4.

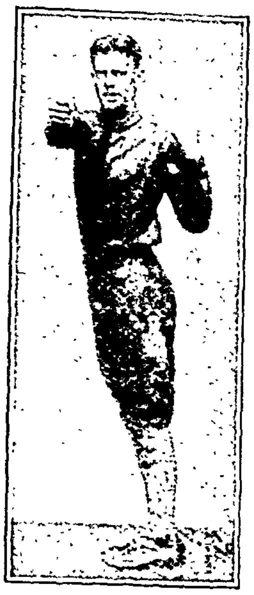

Fig. 15.—Grade V, Exercise 1.

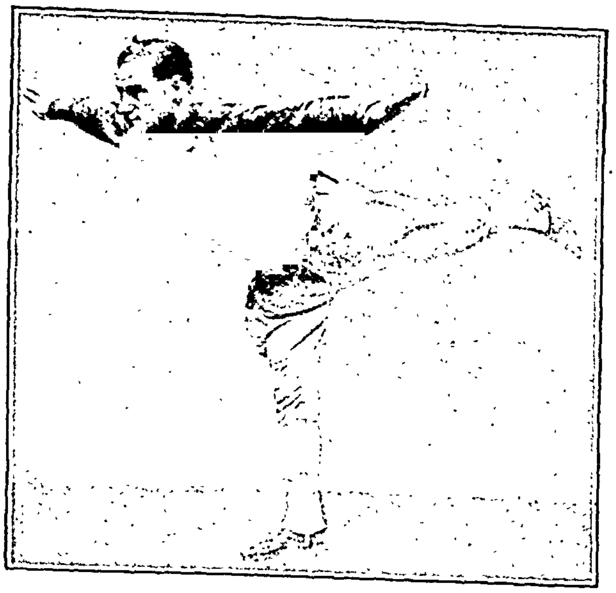

Fig. 16.—Grade V, Exercise 3.

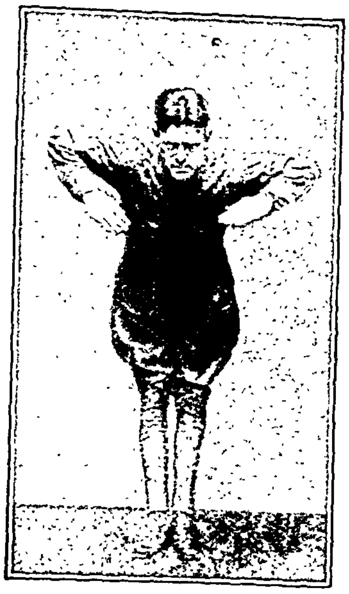

Fig. 17.—Grade V, Exercise 4.

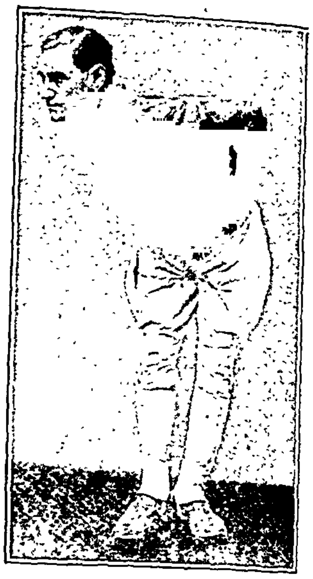

Fig. 19.—Grade V, Exercise 6.

5. Arms bent for thrust: Swing left leg forward—1. Return—2. Right—3, 4. Trunk held erect.
6. Side stride stand: Bend trunk left sideward and raise right arm sideupward—1. Return—2. Left arm—3, 4.
7. March in place (two minutes).
8. Raise arms forupward and inhale. Lower sidedownward and exhale.

Grade III (twenty minutes):
1. Raise arms forupward—1. Return—2. Raise arms sideupward—3. Return—4.
2. Raise arms forward—1. Move arms sideward, raise chest and inhale—2. Return—3, 4.
3. Bend knees and raise arms sideward—1. Return—2.
4. Side stride stand: Hands on hips. Lower trunk forward—1. Return—2.

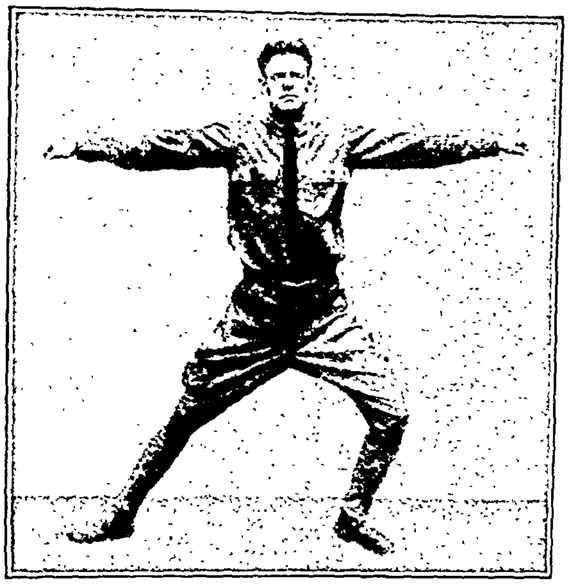

Fig. 18.—Grade V, Exercise 5.

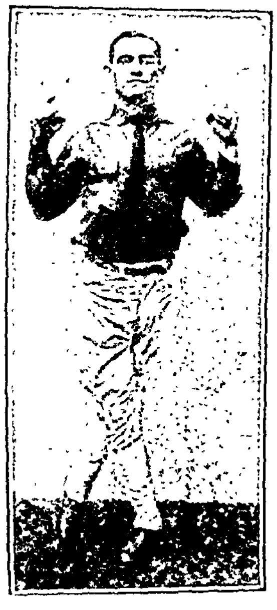

Fig. 20. — Grade VI, Exercise 1.

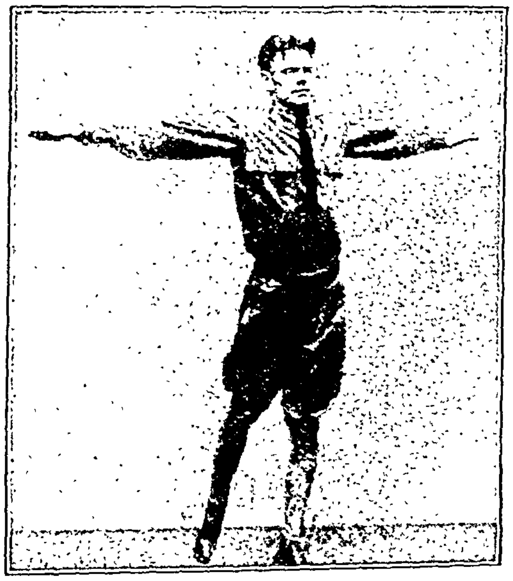

Fig. 21.—Grade VI, Exercise 2.

5. Arms bent for thrust: Swing left leg sideward—1. Return—2. Right—3, 4.

6. Arms bent for thrust, feet closed: Turn trunk left—1. Return—2.
7. Hike, ten minutes; slow, easy step.
8. Raise hands front of shoulders, and inhale—1. Lower and exhale—2.

Grade IV (twenty-five minutes):
1. Raise arms backward—1. Swing arms forupward—2. Return—3, 4.
2. Bend arms for thrust and lower head backward—1. Return—2.
3. Raise left leg forward and arms sideward—1. Return—2. Right—3, 4.
4. Side stride stand: Swing arms forupward—1. Bend trunk forward and touch floor—2. Return—3, 4.
5. Raise heels and raise arms sideupward—1. Bend knees, arms sideward—2. Return—3, 4.
6. Feet closed, arms sideward: Turn trunk left—1. Return—2. Right—3, 4.
7. Hike, fifteen minutes.

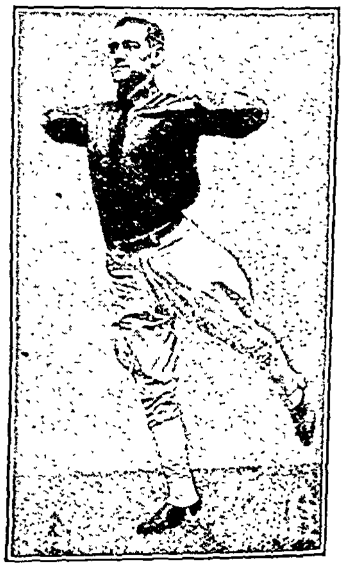

Fig. 22.—Grade VI, Exercise 3.

8. Hands front of shoulders: Straighten arms sideward, palms up and inhale—1. Return and exhale—2.

Grade V (thirty-five minutes):

1. Feet closed, arms bent for thrust: Turn trunk left and thrust right arm forward—1. Return—2. Right—3, 4.
2. Arms bent for thrust: Straighten arms sideward, palms up, raise chest and inhale—1. Return—2.
3. Raise arms sideward and left leg forward—1. Move left leg backward and lower trunk one half forward—2. Return—3, 4.
4. Hands front of shoulders: Lower trunk one half forward and exhale—1. Raise trunk, raise arms sideward and inhale—2.

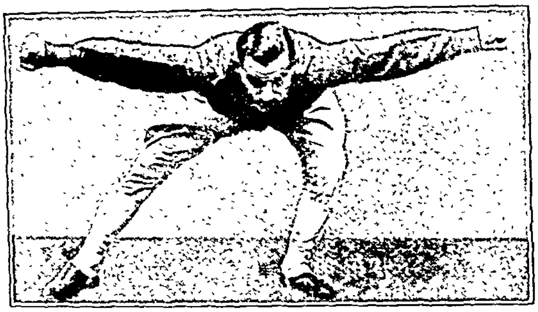

Fig. 23.—Grade VI, Exercise 4.

5. Arms bent for thrust: Lunge left and thrust sideward—1. Return—2. Right—3, 4.
6. Hands on hips: Turn trunk left—1. Bend trunk forward—2. Return—3, 4.
7. Run in place, twenty seconds. Breathing exercises. Repeat the run.
8. Raise arms forward and inhale. Lower sideward and exhale.

The free exercises cover about twenty minutes and should be taken in full time with brisk, snappy rhythm.

Grade VI (sixty minutes):

1. Bend arms for thrust and place left foot backward—1. Lunge left sideward and thrust arms sideward—2. Return—3, 4.
2. Step left forward, raise arms sideward, raise chest and inhale—1. Return—2.
3. Raise left leg backward, hands front of shoulder—1. Lower trunk forward, arms sideward—2. Return—3, 4.
4. Lunge left sideward and bend arms for thrust—1. Thrust arms sideward and lower trunk forward—2. Return —3, 4.

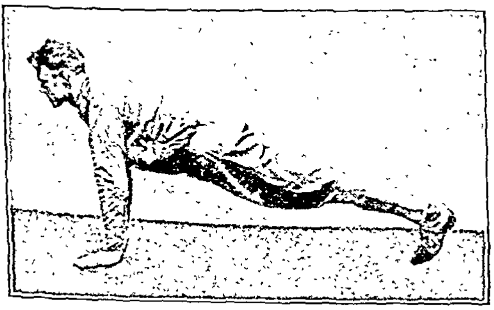

Fig. 24.—Grade VI, Exercise 5.

5. Bend knee and place hands on floor—1. Support lying frontways—2. Bend arms—3. Return—4, 5, 6.
6. Side stride stand, hands on hips: Bend trunk forward —1. Circle trunk left—2. Backward—3. Right—4. Forward—5. Raise trunk—6. Repeat, with circle trunk right.
7. Run in place, one minute.
8. Raise arms forupward and inhale. Lower sidedownward and exhale.

Vigorous game, fifteen minutes. Games: Dodge ball, cage ball, volley ball, relay races, basket ball, tag games, etc.

Hike, twenty minutes. Part of hike in double time and rest in quick time. A swim may be substituted for part of hike.

The exercises are given each morning as outlined. Each afternoon, Grades I, II and III have fifteen minutes of exercises together, and Grades IV, V and VI have fifteen minutes exercises and fifteen minutes hike together.

ANTERIOR DISLOCATION OF ATLAS FOLLOWING TONSILLECTOMY

HAROLD SWANBERG, B.S., M.D. (Salt Lake City)
First Lieutenant, M. C., U. S. Army; Roentgenologist, General Hospital No. 6
FORT MCPHERSON, GA.

This case is so unusual, both as to the etiology and the failure to recognize the condition for a long period, that it is well worth reporting.

REPORT OF CASE

A private, white, aged 22, a farmer before entering the Army, with negative family and past history, was admitted to one of the base hospitals, Dec. 19, 1917, suffering from measles and acute follicular tonsillitis. Tonsillectomy was performed, Jan. 16, 1918; the night of the operation the patient's neck suddenly became stiff, and had remained that way ever since.

He arrived at General Hospital No. 6, in July, 1918, and the following brief history accompanied him: "1. Complaint: Pain in neck, stiffness of cervical muscles which permits of very little motion of the head, except anterior-posteriorly, which motion is limited. 2. Search for focal infection: (*a*) Tonsils (fragments); (*b*) roentgen ray, ostearthritis, first and second cervical vertebrae; (*c*) teeth, abscess tooth; (*d*) Wassermann, negative; (*e*) genito-urinary, negative. 3. Treatment: (*a*) Tonsil fragments removed; (*b*) specimen from tonsil shows gram-negative diplococci; (*c*) tooth removed; (*d*) acetylsalicylic acid for pain, and sodium bicarbonate. Condition on dismissal: No improvement. Etiology: Probably of focal origin (tonsils)."

On arrival of the patient at this hospital, the general condition was good; the weight was normal; the neck was stiff, all motions being resisted in every direction; the soldier held his head in a rigid position with the chin depressed; he complained of pain in the cervical muscles on motion attempted in any direction; he could not rotate his head; he had persistent headaches. The general physical examination was negative except for exaggerated knee reflexes. The diagnosis was undetermined and the patient was sent to the roentgen laboratory for examination.

The roentgen findings were very positive. There was a simple, complete, anterior dislocation of the atlas and skull on the axis (epistropheus), unaccompanied by fracture. Stereoscopic plates showed the odontoid process (dens) free from any bony articulation and intact, the remaining part of the cervical spine being negative. The lateral masses of the atlas were no longer in contact with the superior articular processes of the axis. As the spinal cord must necessarily pass between the odontoid process of the axis and the anterior margin of the posterior arch of the atlas, it seems unreasonable to believe that it would be free from pressure in that small space in a complete anterior dislocation of the atlas, yet the patient had no symptoms of cord pressure. It appears quite evident that the transverse ligament of the atlas (the ligament that holds the odontoid process in contact with the anterior arch of the atlas) was ruptured, for it is hardly reasonable to suppose that the odontoid had slipped from under it. No evidence of ostearthritis was seen in any of the cervical vertebrae. Following the roentgen examination, the nasopharynx was palpated, and the anterior part of the atlas was very easily felt as a large, rounded, bony mass pressing forward and occupying a large part of the cavity.

The soldier was placed under ether anesthesia and manipulation attempted. A gain from 5 to 100 degrees in rotation was noted, and flexion, extension and lateral bending were practically normal. Following the anesthetic the neck appeared more stiff than before, roentgen reexamination showing *no change* in the position of the parts. The soldier declined further manipulations or operation. Suspension of the entire body from the head was of no avail.

COMMENT

There are some very interesting points regarding this case:

1. *History.*—It seems unreasonable to believe that we have the correct history of the case. The tonsillectomy was done under local anesthesia (procain), and this trouble came on suddenly the night of the operation. I have corresponded with the base hospital from which the patient was sent. It is stated that there is no history of trauma, and the patient denies any himself.

Simple anterior dislocation of the atlas.

ANATOMIC POINTS NOTED ON A TRUE LATERAL PLATE OF CERVICAL REGION, OBSERVED IN SIMPLE ANTERIOR DISLOCATION OF THE ATLAS

NORMAL	DISLOCATED ATLAS
1. Posterior pharyngeal wall practically vertical.	1. Posterior pharyngeal wall markedly curved forward, anterior to atlas.
2. Anterior margin of anterior tubercle of atlas in line with anterior margin of body of axis.	2. Anterior tubercle on a more anterior level.
3. Lateral masses of atlas rest on superior articular processes of axis.	3. Lateral masses of atlas on a more anterior level.
4. Odontoid process in contact with anterior arch of atlas.	4. Odontoid process free.
5. Anterior margin of posterior tubercle of atlas on a plane posterior to anterior margin of spinous process of axis.	5. Anterior margin of posterior tubercle on a plane anterior to anterior margin of spinous process of axis.

2. *Error in Diagnosis.*—It is somewhat difficult to believe that such a gross condition as this would pass with a diagnosis of ostearthritis for six months. If any one would have simply palpated or examined the nasopharynx, the condition would have been diagnosed at once. The failure to recognize early such a marked pathologic condition on the roentgen plate seems unpardonable, yet the patient states he was rayed about six times. However, this is the second case of anterior dislocation of the atlas I have observed that has not been recognized on the roentgenogram.

PNEUMONIA AT CAMP FUNSTON

REPORT TO THE SURGEON-GENERAL*

EUGENE L. OPIE, M.D. (ST. LOUIS)
Lieutenant-Colonel, M. C., U. S. Army
ALLEN W. FREEMAN, M.D. (COLUMBUS)
Major, M. C., U. S. Army
FRANCIS G. BLAKE, M.D. (BOSTON)
Captain, M. C., U. S. Army
JAMES C. SMALL, M.D. (CHICAGO)
AND
THOMAS M. RIVERS, M.D. (BALTIMORE)
First Lieutenants, M. C., U. S. Army
CAMP PIKE, LITTLE ROCK, ARK.

This investigation of pneumonia made at the base hospital at Fort Riley includes all cases of pneumonia that have occurred between July 23 and Aug. 31, 1918, at Camp Funston, including Detention Camp No. 1 for white troops and Detention Camp No. 2 for colored troops, in the 311th Cavalry stationed at Fort Riley, at the base hospital, and at the Medical Officers' Training Camp.

During the period of the investigation there has been no large outbreak of pneumonia at Camp Funston. The average number of cases has been two a day, the total number studied being 62. The number of troops in the camp has been approximately 42,000, so that for the month of August the pneumonia rate has not exceeded 1.5 per thousand.

Pneumonia has been of mild type; there have been only three deaths, and empyema has occurred in one instance. The clinical diagnosis has been lobar pneumonia in fifty-five cases and bronchopneumonia in seven cases. The pneumonia observed here has presented no unusual clinical characters, and in the three cases in which necropsy has been performed, there has been lax consolidation of one or more lobes of the lungs.

Pneumonia of this period has in considerable part affected newly drafted negro troops from Southern states, namely, Louisiana and Mississippi. This pneumonia of newly drafted troops has presented characters that deserve special consideration. During our study, cases of pneumonia from two drafts of colored troops have been fairly numerous. In the period from June 19 to 23, 5,982 drafted colored men reached Camp Funston, and were sent to Detention Camp No. 2, located 5 miles from Camp Funston. They were held in detention camp two or three weeks, until assigned to units stationed at Camp Funston. Among these drafted men, between June 15 and August 31, sixty-nine cases of pneumonia have occurred. Among 12,000 white men drafted in June there has been only one case of pneumonia.

---

* Because of lack of space, this article is abbreviated in THE JOURNAL by omission of Tables 3 and 13. The complete article will appear in the authors' reprints.

In July there was a similar outbreak of pneumonia in 5,997 newly drafted negroes. They were in great part from Mississippi, and entered Detention Camp No. 2 from July 16 to 20. The greater number of these men were transferred to Camp Funston after periods of from two to three weeks. Among them, in the period from their arrival to August 31, there have been twenty cases of pneumonia. Among 15,000 white troops drafted in July, from the 22d to 27th, eight developed pneumonia.

The incidence of pneumonia among troops in Camp Funston (Chart 1) from June 15 to August 31 is given in Table 1.

These figures suggest at first sight that pneumonia is much more common in colored than in white troops, but an analysis of the state of origin of newly drafted colored men shows that comparison is possible only between men from the same states (Table 2).

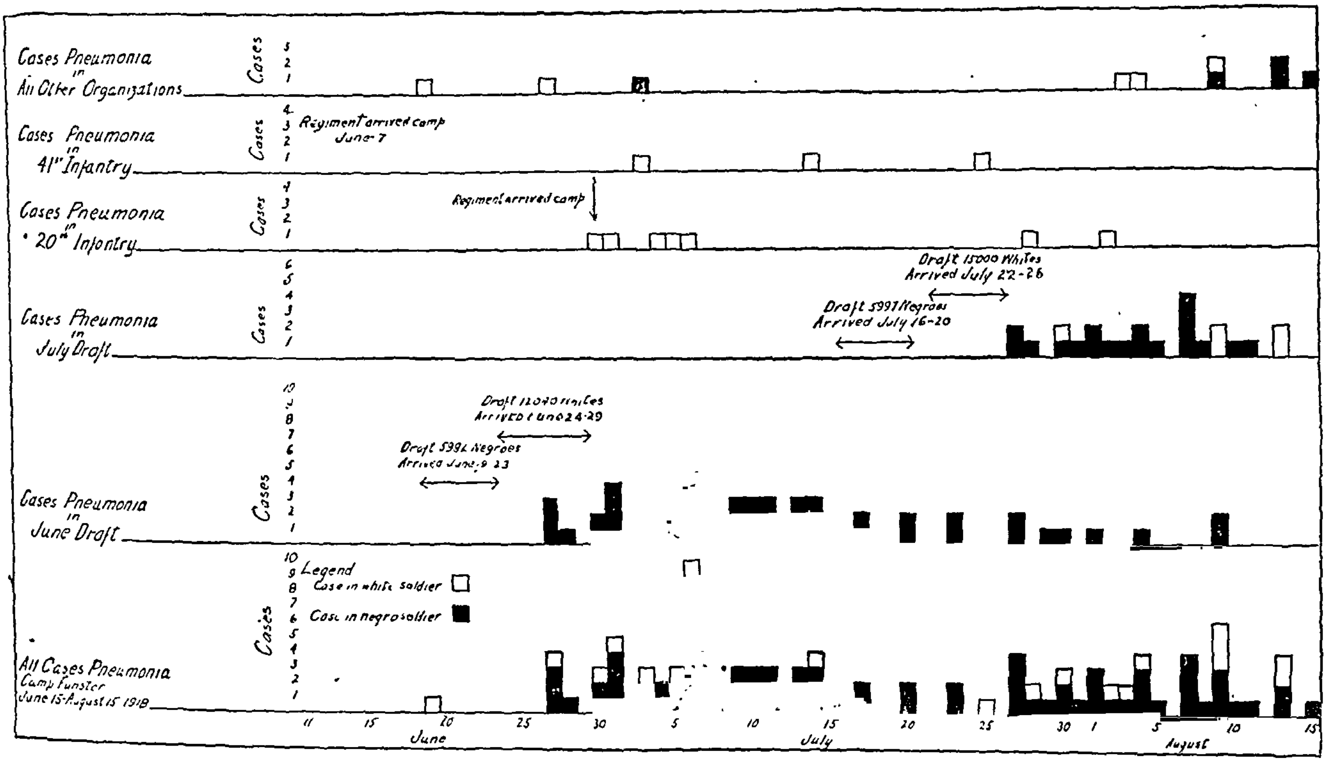

Chart 1.—Pneumonia at Camp Funston, from June 15 to Aug. 15, 1918.

Figures for one draft are not comparable with those from another, because the periods of observation differ, and departure from the camp of units formed from different drafts modifies the exact accuracy of the figures for each draft; but these factors will not alter the relations indicated in the table. Pneumonia has been common in negro drafts from different states in the order of their geographic location from south to north, namely, Louisiana, Mississippi (factor of time prevents comparison of these two states), Oklahoma, Missouri, Kansas and Nebraska. It is evident that the white and colored drafts cannot be compared, since none of the white troops came from Louisiana and Mississippi.

TABLE 1.—INCIDENCE OF PNEUMONIA AT CAMP FUNSTON

	No. of Troops	Pneumonia No. of Cases	 Per Thousand
White			
In Camp Funston prior to June 15..	14,198	7	0.49
20th Infantry, which arrived June 30	2,278	8	3.51
June draft	12,000	1	.08
July draft	15,000	8	.53
August draft	6,006	0	.00
Total	49,482	24	.48

Total	17,613	94	5.34

TABLE 2.—PNEUMONIA AMONG COLORED TROOPS ACCORDING TO STATES

Drafts of Colored Men by States:	No. of Troops	Pneumonia No. of Cases	 Per Thousand
June:			
Missouri	482	0	.00
Oklahoma	500	2	4.00
Louisiana	5,000	67	13.40
July:			
Kansas	1,009	0	.00
Missouri	988	0	.00
Mississippi	4,000	19	4.75
August:			
Nebraska	236	0	.00
Kansas	468	0	.00
Missouri	3,230	2	.62

BACTERIOLOGIC STUDY OF PNEUMONIA

In view of the selective occurrence of pneumonia in newly drafted colored troops from Louisiana and Mississippi, it is important to know the etiologic factors concerned in the production of the pneumonia that has occurred. Bacteriologic study has been made of the sputum of all pneumonia patients entering the base hospital between July 23 and August 31 (Table 3). White mice have been inoculated intraperitoneally with sputum, and the Avery method for identification of pneumococci has been used. Cultures from throat swabs have been examined.

The incidence of pneumococcus, *Streptococcus hemolyticus* and *Bacillus influenzae* in the sputum of newly drafted negroes is given in Table 4. The observations made on the June draft are almost wholly limited to colored men from Louisiana, exceptions being one case from Mississippi and one from Oklahoma; observations for the July draft are on negroes from Mississippi.

With pneumonia of drafted colored men from Louisiana and Mississippi, organisms which are frequently found in the mouths of normal individuals, namely, pneumococcus IV, III and Atypical II, have been found in twenty-five of thirty-five cases, that is, in 71 per cent. No pneumococci of Type II were found. In contrast to this relation, the distribution of various pneumococcus types among pneumonia patients from a variety of organizations located at or near Camp Funston has closely approximated that of civil life, Types I and II constituting the greater number of cases. Among these miscellaneous cases of pneumonia, the percentage of mouth types has been only 37.5 per cent., in sharp contrast with that found in the pneumonia among newly drafted Southern negroes. Of eight white men with pneumonia from the July draft (four from Missouri and four from Kansas), four (50 per cent.) had pneumococcus Type I, two Type II (25 per cent.), and two Type IV (25 per cent.).

TABLE 4.—ORGANISMS IN SPUTUM OF NEWLY DRAFTED NEGROES

JUNE DRAFT

Pneumococcus, Type I	6
Pneumococcus, Type II	0
Pneumococcus, Type II, atypical	3
Pneumococcus, Type III	1
Pneumococcus, Type IV	5
Hemolytic streptococcus alone	0
Total	15

Bacillus influenzae was found in two instances, associated with pneumococcus Type I. Hemolytic streptococcus was found in throat swab once with pneumococcus atypical Type II, once with Type IV. It was not present in the sputum of these patients.

JULY DRAFT

Pneumococcus, Type I	3
Pneumococcus, Type II	0
Pneumococcus, Type II, atypical	4
Pneumococcus, Type III	4
Pneumococcus, Type IV	8
Hemolytic streptococcus alone	1
Total	20

Bacillus influenzae has been found once, associated with pneumococcus atypical Type II, once with Type III, and once with Type IV. Hemolytic streptococcus has been found in throat swab once with bronchopneumonia. The sputum of this patient contained pneumococcus atypical Type II, but no hemolytic streptococci.

For completeness, the three cases of pneumonia from the August draft are cited below:

AUGUST DRAFT

Pneumococcus, Type I	1
Pneumococcus, Type II, atypical	1
Pneumococcus, Type IV	1
Total	3

For comparison with the pneumonia of the June and July drafts cited above, other cases of pneumonia scattered among eleven organizations, and with three exceptions in white men, are summarized below.

From eleven organizations at or near Camp Funston:

Pneumococcus, Type I	9
Pneumococcus, Type II	5
Pneumococcus, Type II, atypical	0
Pneumococcus, Type III	1
Pneumococcus, Type IV	8
Hemolytic streptococcus alone	1
Total	24

Bacillus influenzae has been found once in association with pneumococcus Type II and twice with Type IV. Hemolytic streptococci have been found in throat swab once with Type I (also in sputum), once with Type III, and once with Type IV.

It is noteworthy that two of the small number of cases of Type I pneumonia among Louisiana negroes, and two among Mississippi negroes, occurred in one small unit, namely, the Twenty-Second Provisional Company of the 164th Depot Brigade, a body containing 250 men. It seems not improbable that the members of this company were brought into contact with Type I pneumococcus after formation of the company. An examination of the saliva of twenty-five healthy members of this company disclosed one man who harbored in his mouth pneumococcus Type I.

Among sixty-two cases of pneumonia, pneumococcus Type II was found only five times. It is noteworthy that two of these four instances of Type II occurred in a small body of enlisted men of the Medical Officers' Training Camp in Quarters 4 M, consisting of a group of tents. The onset of the second of these cases was on August 17. August 22 the saliva of thirty-two men then in these quarters was examined for penumococcus. No carriers of pneumococcus Type II were found.

Pneumococci and Other Bacteria in Mouths of Healthy Men in Military Organizations at Camp Funston.—Since the groups of cases that have been mentioned show variations, it has seemed desirable to determine if corresponding variations might be found in the incidence of pneumococcus in the mouths of healthy men of the organizations in which pneumonia occurred. It was further desirable to determine if carriers of pneumococcus Types I and II were present in units in which several instances of corresponding types of pneumonia had occurred. At the time of the investigation colored troops in Detention Camp No. 2, where pneumonia had been most prevalent, were in large part from the July draft.

Saliva from twenty-five men of the Twenty-Second Provisional Colored Company of the 164th Depot Brigade was injected into the peritoneal cavities of mice, and the micro-organisms that developed were determined (Table 5). This company was selected because four instances of pneumonia, due to pneumococcus Type I, had occurred in it.

TABLE 5.—ORGANISMS IN SALIVA OF MEN OF 164TH DEPOT BRIGADE, 22D PROVISIONAL COLORED COMPANY

	Number	Per Cent.
Pneumococcus, Type I	1	4
Pneumococcus, Type II	0	0
Pneumococcus, Type II, atypical	1	4
Pneumococcus, Type III	2	8
Pneumococcus, Type IV	13	52
No pneumococci found	8	32
Total	25	

Bacillus influenzae was found six times, and *Streptococcus hemolyticus* once.

Since twelve of our cases of pneumonia occurred in the Third Development Battalion, an organization in which colored men partially disqualified for military service are given training, this organization was next selected for study. The saliva of twenty-five men from Company D was examined, with the result given in Table 6.

For comparison with the observations made on colored organizations, saliva from twenty-five white men was tested (Table 7). The Seventieth Infantry was selected because no pneumonia had occurred in this organization within the period of our observation.

Examination of the records of the hospital showed that the man from whom pneumococcus Type I was obtained had been admitted to the base hospital, May 27, 1918, and returned to duty, July 10, five weeks before examination of the saliva. While in the hospital he suffered with acute bilateral suppurative otitis media and pyorrhea alveolaris; tonsillectomy was performed.

The saliva of twenty-seven men from the 210th Engineers, a white regiment in which no pneumonia had occurred during our study, was examined, with the results given in Table 8.

TABLE 6.—ORGANISMS IN SALIVA FROM MEN OF THIRD DEVELOPMENT BATTALION, CO. D

	Number	Per Cent.
Pneumococcus, Type I	0	0
Pneumococcus, Type II	0	0
Pneumococcus, Type II, atypical	3	12
Pneumococcus, Type III	3	12
Pneumococcus, Type IV	6	24
No pneumococci found	13	52
Total	25	

Bacillus influenzae was found eleven times. *Streptococcus hemolyticus* five times, and *Bacillus mucosus-capsulatus* twice.

TABLE 7.—ORGANISMS IN SALIVA OF MEN OF SEVENTIETH INFANTRY

	Number	Per Cent.
Pneumococcus, Type I	1	4
Pneumococcus, Type II	0	0
Pneumococcus, Type II, atypical	1	4
Pneumococcus, Type III	1	4
Pneumococcus, Type IV	15	60
No pneumococci found	7	28
Total	25	

Bacillus influenzae was found eleven times, and *Streptococcus hemolyticus* twice.

In view of the occurrence of two cases of pneumonia associated with pneumococcus Type II, in Quarters 4 M of the Medical Officers' Training Camp, five days after the admission of the second of these patients with Type II pneumonia to the hospital, search was made for pneumococci in the mouths of thirty-two men from the squad occupying these quarters. The examination of these normal men had the result given in Table 9.

The observations indicate that approximately two thirds of the men in the organizations examined harbor pneumococci, with few exceptions belonging to the groups that have heretofore been found in the mouths of healthy men. In view of the uniformity of the results obtained, the examinations were discontinued.

The high incidence of *Bacillus influenzae* in the mouths of healthy men is noteworthy. It serves as a basis for comparison with conditions such as influenza, bronchitis, and other diseases of the respiratory passages. Its significance in relation to the existence of an epidemic of influenza in this camp during March, April and May cannot be determined.

COMMENT

The foregoing study has shown that lobar pneumonia caused by pneumococcus has occurred with unusual frequency among negroes drafted from Louisiana and Mississippi. The types of pneumococcus concerned are in great part those that occur in the mouths of healthy individuals, namely, Atypical Type II, Type III and Type IV. Type I has been less frequent than with the pneumonia of civil life, and Type II has not been found in this group of cases. Predominance of mouth types has been more conspicuous in the more recently drafted troops from Mississippi.

To explain the occurrence of this pneumonia of newly drafted men, two groups of factors may be considered: First, conditions that depress resistance, such as exposure to cold or wet, exposure to dust, fatigue from the unusual exertions of military training, and the reaction from typhoid-paratyphoid inoculation. Second, conditions that favor transmission of various respiratory infections, when large numbers of men are brought into intimate contact with one another.

We have obtained no evidence that these negro drafts which have developed pneumonia have been exposed to cold or wet during transportation to the camp, or after their arrival. Organizations in which pneumonia has prevailed have not been exposed to dust in greater degree than those which have been relatively free from it. Negro troops at Detention Camp No. 2 have not been required to perform prolonged or severe drill; their work has not been heavier than that of white troops.

There is little support for the suggestion that typhoid inoculation has had any part in the production of the disease. Although white drafts and colored drafts, both from Missouri and Kansas, and from Mississippi and Louisiana, have all been subjected to the same procedure, pneumonia has been conspicuously selective.

TABLE 8.—ORGANISMS IN SALIVA OF MEN OF 210TH ENGINEERS

	Number	Per Cent.
Pneumococcus, Type I	0	0.0
Pneumococcus, Type II	0	0.0
Pneumococcus, Type II, atypical	1	3.7
Pneumococcus, Type III	1	3.7
Pneumococcus, Type IV	14	51.9
No pneumococci found	11	40.7
Total	27	

Bacillus influenzae was found three times, *Streptococcus hemolyticus* once, and *Bacillus mucosus-capsulatus* once.

TABLE 9.—ORGANISMS IN MOUTHS OF MEN FROM QUARTERS 4 M, MEDICAL OFFICERS' TRAINING CAMP

	Number	Per Cent.
Pneumococcus, Type I	0	0.0
Pneumococcus, Type II	0	0.0
Pneumococcus, Type II, atypical	1	3.1
Pneumococcus, Type III	2	6.3
Pneumococcus, Type IV	21	65.6
No pneumococci found	8	25.0
Total	32	

Bacillus influenzae was found sixteen times, *Streptococcus hemolyticus* twice, and *Bacillus mucosus-capsulatus* four times. No carriers of pneumococcus Type II were found.

The small number of cases of pneumonia under observation has offered scant opportunity to study the epidemiology of various types classified with regard to the type of infecting pneumococcus. The small amount of evidence at hand tends to favor the view that susceptible individuals from far Southern states are brought into intimate contact, perhaps for the first time, with types of pneumococci capable of producing in them lobar pneumonia. These types are at first widely distributed pneumococci, such as frequently occur in the mouths of normal individuals. We have obtained some evidence to support the view that introduction of Type I pneumococcus into a group of drafted Southern negroes is followed by pneumonia referable to this organism. Four of the nine cases of Type I pneumonia occurred in the Twenty-Second Provisional Company of the 164th Depot Brigade, and examination of twenty-five healthy men from this company disclosed one carrier. The absence of Type II pneumonia among drafted negroes from Louisiana and

Mississippi indicates that they had not come into contact with the corresponding pneumococcus.

HEMOLYTIC STREPTOCOCCI

Among the cases of pneumonia that we have studied, hemolyzing streptococci have had an insignificant part. There have been only two cases of pneumonia in which the result of bacteriologic examination has suggested that this organism was concerned in the production of the disease. There has been no evidence that streptococci have produced complications during the course of pneumonia caused by pneumococci. During the period of our study, 112 patients with measles have been admitted to the base hospital at Fort Riley. There has been no instance of associated pneumonia, and otitis media, the sole complication, has occurred in only two instances. In both cases, staphylococci were obtained from the discharge.

Hemolytic Streptococci in the Throats of Healthy Men.—Observations on the occurrence of hemolytic streptococci in the mouths of normal men and of patients with measles and with pneumonia have been made here in order to explain, if possible, the infrequency of those respiratory complications due to streptococci which have greatly increased the severity of measles in some other camps.

In swabbing the throat the attempt was made to produce gagging. The swab was then quickly touched to both tonsils and lastly to the pharynx. The swab was introduced into a tube containing broth, and freely twirled. The broth tube was brought to the laboratory, and melted agar-agar containing 5 per cent. of defibrinated horse blood was inoculated with a loopful of the broth and poured into a Petri plate. A second loopful of the broth was streaked over the surface of one half of the plate, when solidified. Hemolytic streptococci were identified by the methods for the isolation and identification of *Streptococcus hemolyticus* adopted by the Medical Department of the Army.

The throats of 274 men on duty have been examined in the organizations listed in Table 10.

TABLE 10.—INCIDENCE OF HEMOLYTIC STREPTOCOCCI

	Number Examined	Hemolytic Streptococci Present	Per Cent. with Hemolytic Streptococci
White men:			
70th Infantry	24	4	16.7
210th Engineers, Co. C	26	6	23.1
164th Depot Brigade, Co. 15	50	10	20.0
164th Depot Brigade, Co. 18	51	13	25.5
164th Depot Brigade, Co. 28	50	13	26.0
Total	201	46	22.9
Colored men, all from Detention Camp No. 2:			
164th Depot Brigade, Prov. Co. 22	25	6	24
3d Development Bn., Co. A	24	3	12.5
3d Development Bn., Co. D	24	5	20.8
Total	73	14	19.2
Men resident in the hospital:			
Laboratory workers	10	3	30.0
Patients in surgical ward	14	4	28.6
Total	24	7	29.2

The figures cited indicate that one in four or five of healthy men in this camp harbor hemolytic streptococci, and this proportion is not materially influenced by residence in the hospital.

Hemolytic Streptococci with Measles.—In view of the foregoing observation, it was surprising to find that hemolytic streptococci were present in only three of 112 measles patients at the time of their admission to the hospital. The hospital routine for measles is as follows: After a throat swab has been made, the throat is gargled with 20 per cent. argyrol, and sprayed with argyrol three times a day. The same solution is dropped into the conjunctival sac to relieve discomfort caused by conjunctivitis. Patients in bed are separated by sheets. Convalescent patients are not strictly segregated, and assist in the care of patients in bed. Face masks are not worn. Hemolytic streptococcus carriers remain in the ward. Eating utensils are sterilized. Complications due to streptococcus have not been present during the period of our investigation.

The incidence of hemolytic streptococci in the throats of patients with measles (Table 11A), was very small on admission, but later on in the disease gradually increased. On admission to the hospital only three of 112 patients with measles harbored hemolytic streptococci. In a period from the third to the tenth day in the hospital, eighty-six patients were reswabbed and hemolytic streptococci were found in eleven (12.8 per cent.); between the eighth and the twenty-third day, fifty-eight were swabbed a third time, and fourteen (24.1 per cent.) were found to carry the organism.

TABLE 11.—HEMOLYTIC STREPTOCOCCI WITH MEASLES AT CAMP FUNSTON

A. All Measles Patients Admitted to the Wards

	Days in Hospital	Approximate Day of Disease	No. of Patients Swabbed	Number with Hemolytic Streptococci	Per Cent. with Hemolytic Streptococci
First swabbing	0 to 1	1 to 8	112	3	2.67
Second swabbing	3 to 10	4 to 16	86	11	12.79
Third swabbing	8 to 23	12 to 26	58	14	24.14

The first swabbing represents the findings on admission, in the series of 112 cases; 86 patients were swabbed twice; 58 patients were swabbed three times.

B. Hemolytic Streptococci with Measles in 164th Depot Brigade, Company 28

	Days in Hospital	No. of Those Swabbed	Number with Hemolytic Streptococci	Per Cent. with Hemolytic Streptococci
First swabbing	0 to 1	23	0	0
Second swabbing	3 to 9	23	4*	17.39
Third swabbing	10 to 21	21	4	19.05
Normal men of Co. 28		50	13	26.00

* Two cases positive for hemolytic streptococci on this swabbing were negative on subsequent swabbing.

This is a comparison of the percentage of carriers among patients with measles spending less than ten days in the hospital, and that of patients spending more than ten days in the hospital; it also compares the percentage of carriers among the convalescents from measles and that among the normal men on active duty in the same company.

C. Hemolytic Streptococci with Measles in Seventieth Infantry

First swabbing	0 to 1	38	0	0
Second swabbing	5 to 9	25	1	4.0
Third swabbing	8 to 17	12	2	16.7
Normals on duty with 70th Inf.		24	4	16.7

This represents a series of 38 cases of measles from the 70th Infantry and the findings on admission. It shows that 25 patients were swabbed twice, with the results of the second swabbing made after from 5 to 9 days in the hospital; it shows that 12 patients were swabbed three times, and the findings on third swabbing after from 8 to 17 days in the hospital. A series of normals from the same organization is introduced for comparison.

Comparison of these figures for measles with those for normal men suggests the possibility that hemolytic streptococci temporarily disappear from the throat during the early stage of measles, at a time when the rash is present. During the period of our study, an outbreak of measles occurred in the Twenty-Eighth Company of the 164th Depot Brigade; twenty-three patients from this company were admitted to the hospital (Table 11B). On admission, throat swabs disclosed no carriers of hemolytic streptococcus, yet subsequent examinations, made between the third and the ninth day after admission, demonstrated that four of twenty-three patients (17.4 per cent.) harbored hemolytic streptococci; between the tenth and twenty-first days, four of twenty-one patients examined (19.1 per cent.) were found to be carriers of the organism. The throats of fifty healthy men in Company 28 were examined, and 26 per cent., a figure closely approximating that obtained for other organizations, were found to contain hemolytic streptococci.

From various companies of the Seventieth Infantry, thirty-eight patients with measles were admitted to the hospital (Table 11C), and no hemolytic streptococci were found in admission. Subsequently hemolytic streptococci were obtained from the throats of one of twenty-five men examined from the fifth to the ninth day of their stay in the hospital, and among twelve examined from the eighth to the seventeenth day, hemolytic streptococci were found in two (16.7 per cent.). Many of these cases of measles occurred late in August, and could not be followed throughout their stay in the hospital. From various companies of the Seventieth Infantry, twenty-four men on duty were examined, and four (16.7 per cent.) were found to harbor hemolytic streptococci. The observations made on these two organizations furnish further evidence that hemolytic streptococci have temporarily disappeared from the throats of men attacked by measles.

Hemolytic Streptococci with Pneumonia.—Throat swabs were made from sixty-one cases of pneumonia. In eight, hemolytic streptococci were found; in two instances of bronchopneumonia, hemolytic streptococci, but no pneumococci, were found in the sputum, and there is little doubt that pneumonia was caused by hemolytic streptococci. In one instance, hemolytic streptococci were found in the sputum but not in the throat swab. It is noteworthy that the proportion of patients with pneumonia harboring hemolytic streptococci, 14.8 per cent., is less than that of the normal men.

BACTERIOLOGY OF BRONCHITIS

With the purpose of determining what micro-organisms are associated with bronchitis, and the possible relation of this disease to bronchopneumonia, throat swabs were made in the small number of cases, namely, thirteen, available for study, and at the same time sputum was injected into mice. The results of bacteriologic examinations are given in Table 12.

TABLE 12.—BACTERIOLOGIC FINDINGS IN BRONCHITIS

	Throat Swab	Sputum
1.	Negative	B. influenzae and Pneumococcus IV
2.	Hemolytic streptococcus	No examination
3.	Hemolytic streptococcus	No examination
4.	Negative	Pneumococcus IV
5.	Hemolytic streptococcus	Pneumococcus IV
6.	Negative	B. influenzae and Pneumococcus IV
7.	Hemolytic streptococcus	No examination
8.	Negative	B. influenzae and Pneumococcus IV
9.	Negative	B. influenzae and Pneumococcus IV
10.	Negative	B. influenzae and Pneumococcus IV
11.	Negative	B. influenzae and Pneumococcus II atypical
12.	Negative	Pneumococcus IV
13.	Negative	B. influenzae and Pneumococcus IV

Pneumococcus Type IV or in one instance Atypical Type II was found in all cases in which the sputum was examined. In four of thirteen cases (30.7 per cent.) hemolytic streptococci were found. This proportion, uncertain by reason of the small number of cases, is greater than that found in Camp Funston among normal men.

Bacillus influenzae was found in seven of thirteen cases of bronchitis, that is, in 53.8 per cent. of the cases examined and in 70 per cent. of those examined by mouse inoculation. The highest percentage of incidence of *Bacillus influenzae* in any group of normal men was 50 per cent. in men from Quarters 4 M, Medical Officers' Training Camp, examined by mouse inoculation. In cases of bronchitis with *Bacillus influenzae* and in one case with *Streptococcus hemolyticus* these organisms were associated with pneumococci.

It is significant that either hemolytic streptococci or *Bacillus influenzae* was found in all but two of thirteen cases of bronchitis. Even should we assume that none of these organisms is the primary cause of the disease, it is probable that their multiplication and doubtless their invasion of the lower respiratory passages has occurred with it.

There has been no opportunity to study the bacteriologic flora of the throat or of the sputum of patients suffering with cases diagnosed as influenza.

HISTORY OF PNEUMONIA AT CAMP FUNSTON

It has seemed to us desirable to obtain an insight into the history of pneumonia at the camp since its organization so that we might determine what types of pneumonia have occurred and what relation they bear to the outbreak that we have observed. Through the cordial cooperation of the officers of the hospital, we have tabulated from the records the incidence of pneumonia from the establishment of Camp Funston in August, 1917, up to the present date, Aug. 31, 1918. Chart 2 shows changes in the incidence of pneumonia. Primary pneumonia, pneumonia secondary to measles and a very small group of pneumonias definitely secondary to scarlet fever, diphtheria, mumps and surgical operations have been charted separately.

To obtain further insight into the relationship of pneumonia to other diseases, conditions affecting the air passages have been charted, namely, bronchitis and a disease that has been designated "influenza."

From Sept. 20, 1917, to November 8, with an increasing number of newly recruited troops in the camp, there was a gradual increase in the number of cases of pneumonia. Subsequently with slight fluctuation, there has been a continuous incidence of from one to five or even more cases per day, interrupted at only one time, namely, from May 26 to June 26, 1918, when pneumonia well-nigh disappeared. This relatively steady incidence has been twice augmented by sharply defined outbreaks of pneumonia, namely, (1) between November 8 and December 25, when cases of pneumonia following measles occurred in large number, and (2) between March 1 and May, 26, 1918, when there was a far greater number of cases of pneumonia occurring in very accurate conformity with an outbreak of influenza.

Outbreak of Pneumonia Due to Measles from Nov. 8 to Dec. 25, 1917.—By its relation to measles, this group of cases is sharply defined. Pneumonia was designated bronchopneumonia in ninety-two cases (78.6 per cent.) and lobar pneumonia in twenty-five cases (21.4 per cent.). It was associated with a high incidence of empyema and a mortality of 45.3 per cent. The disease doubtless exhibited close similarity with the pneumonia following measles studied elsewhere.

Outbreak of Pneumonia Occurring in Association with Influenza Between March 1 and May 26, 1918.—Before considering this subject, it is desirable to describe the disease which has been diagnosed influenza, which prevailed continuously since the establishment of the camp, and which within a few days swept as a great epidemic through Camp Funston. The disease, save in very mild cases, was accompanied by fever with elevation of temperature to from 99 to 102 or 103 F. The patient was prostrated, had severe headache, and complained of aching pains in the muscles of the back of the neck, of the lumbar region and at times of the arms or legs. Only a few patients had coryza; and cough, with other evidence of bronchitis, was unusual. With physical signs of bronchitis this diagnosis was added to that of influenza. At the beginning of the outbreak of the disease some patients were sent to the meningitis ward as suspects on account of headache and pain in the back of the neck. Some patients had abdominal pain and were first sent to the surgical ward. Later it became evident that there were no characteristic physical signs associated with the disease. After from twenty-four to forty-eight hours the temperature fell and the patient felt better.

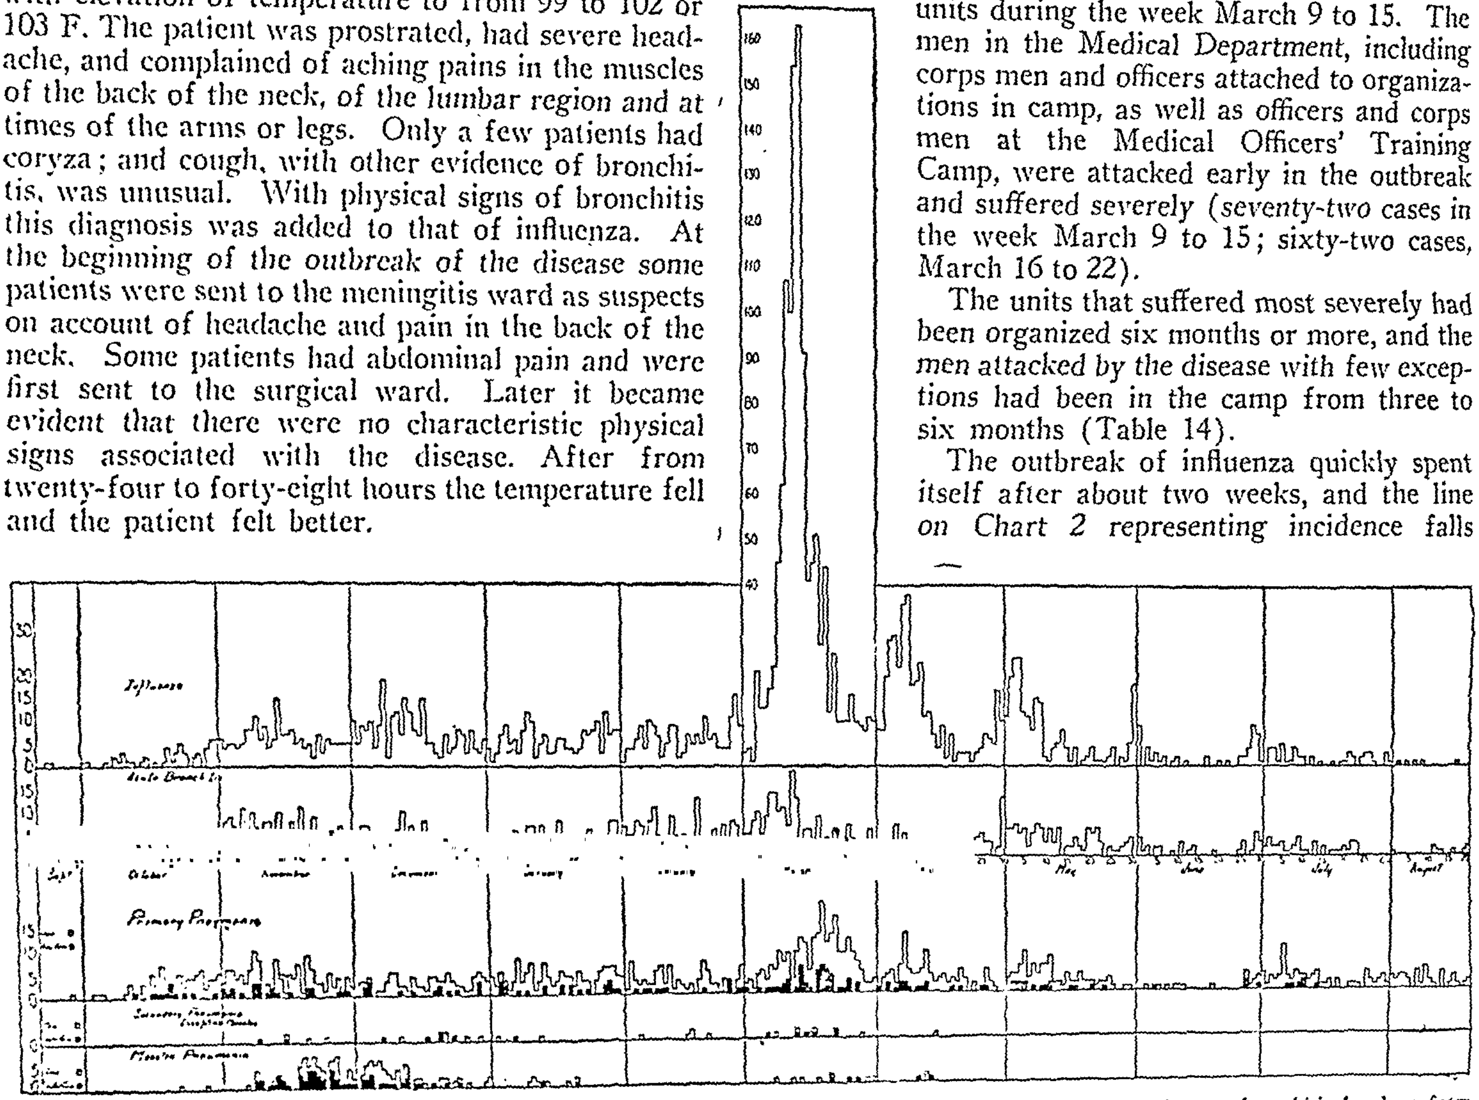

Chart 2.—Respiratory diseases at Camp Funston: admissions to base hospital from pneumonia, influenza, and acute bronchitis by days from Sept. 20, 1917, to Aug. 20, 1918.

Between March 4 and March 29, 1,127 men from Camp Funston, which then contained 29,000 men, were sent to the base hospital with the disease just described, and many more were cared for in the infirmaries of the camp. A dust storm occurred, Saturday, March 9, and on Monday, March 11, 107 patients with "influenza" were admitted to the hospital; from the 342d Field Artillery alone thirty-eight enlisted men and six officers were admitted. This explosive outbreak is well shown on the chart. The ascent of the line representing incidence of the disease before March 9 gives little support to the view held by many who observed the outbreak, that the dust storm was responsible for it.

Table 13 shows the incidence of influenza in various organizations. The first units attacked by the outbreak in March were the 164th Depot Brigade (*white*) with fourteen cases in the week March 2 to 8, eighteen cases, March 9 to 15, and seventy-seven cases, March 15 to 22; and the 317 Headquarters Trains of the Ninety-Second Division, in which thirteen cases occurred on March 8 and forty-nine additional cases in the following week. The 342d Field Artillery was attacked early; it had suffered with the disease more severely than other units in the camp during the entire time since the organization of the camp in September. From this regiment, 163 patients were admitted to the hospital during the week March 9 to 15, but in the subsequent weeks there were few cases.

Every organization in the camp except the 314th Engineers and 341st Artillery was attacked; only five patients were admitted to the hospital from these two units during the week March 9 to 15. The men in the Medical Department, including corps men and officers attached to organizations in camp, as well as officers and corps men at the Medical Officers' Training Camp, were attacked early in the outbreak and suffered severely (seventy-two cases in the week March 9 to 15; sixty-two cases, March 16 to 22).

The units that suffered most severely had been organized six months or more, and the men attacked by the disease with few exceptions had been in the camp from three to six months (Table 14).

The outbreak of influenza quickly spent itself after about two weeks, and the line on Chart 2 representing incidence falls as suddenly as it rose. The disease did not disappear, but the daily incidence was not much in excess of that prior to the outbreak. Later at intervals of somewhat less than one month, a second, a third and even a fourth and fifth wave of the disease is represented in the admissions to the hospital. Each is less severe than the one preceding. The second wave, beginning April 3, reached a maximum on April 8, twenty-five days after that of the primary outbreak, and then quickly disappeared within ten days after its onset. It was almost wholly confined to the 164th Depot Brigade and affected with few exceptions white and colored drafts which had arrived at the camp four or five days before the onset of the disease.

The third wave of influenza began April 28 and reached a maximum on May 3, twenty-six days after that of the second. This outbreak occurred in a group of recently drafted white men in the Depot Brigade. They were attacked one or two days after their arrival. The outbreak lasted about two weeks.

A fourth insignificant outbreak is represented by a group of twenty-seven cases which occurred from May 30 to June 1 in a group of drafted white men who had been in camp eight days. These cases occurred several days after the drafted men had been attached to the Fortieth Infantry. June 25, a few more cases occurred in colored men drafted from five to eight days.

This disease having the characteristics commonly attributed to influenza is not one marked by characteristic symptoms. In the presence of an outbreak, such as that just described, there can be no doubt concerning its identity, even in the absence of bacteriologic studies. It seems probable that occasional cases are recognized with much less certainty. Nevertheless, there is a remarkable similarity between the curve representing the incidence of influenza and that representing primary pneumonia, and to a less degree that representing bronchitis from the establishment of the camp to the present date. There had been a continued fairly high but fluctuating incidence of all three diseases until March of the present year. It is significant that the greatest incidence of pneumonia affecting troops in this camp occurred from March 9 to March 29, coincident and immediately following the first outburst of influenza, the maximum for pneumonia being five days after the maximum for influenza. Coincident with the two subsequent waves of influenza there were corresponding exacerbations in the incidence of pneumonia, the maximal points for influenza and pneumonia being almost coincident on April 7 to 8 and again on May 5 to 6; but in general, pneumonia has lagged behind influenza. The coincidence of influenza and pneumonia is further emphasized by the almost complete disappearance of the two diseases in the period from June 3 to 26 and their subsequent reappearance at the end of June and again to a slight extent in July.

To obtain further evidence of the relation of the outbreak of pneumonia to that of influenza, incidence of the two diseases in the organizations attacked has been compared (Table 13). With each wavelike outbreak of influenza there has been a similar outbreak of pneumonia, limited almost entirely to the organizations that had suffered with influenza. Following the first outbreak of influenza, which attacked both old and new organizations, there was a similar widely scattered prevalence of pneumonia. The organizations that suffered most severely were the 164th Depot Brigade, the Medical Department and the 317th Headquarters Trains of the Ninety-Second Division and the 314th Trains (white). These organizations had all suffered very severely with influenza. Organizations which showed the highest incidence of bronchitis were the same as those which suffered most severely with influenza, namely the Depot Brigade (white), the Medical Department, the 342d Field Artillery and the 317th Trains (colored) of the Ninety-Second Division and the 314th Trains (white).

Accompanying the second wave of influenza, which attacked white and colored drafts of the 164th Depot Brigade and reached its maximum on April 8, there was an outbreak of pneumonia limited to the white and colored sections of the draft organization.

Accompanying the third wave of influenza, which was in part limited to the white drafts of the 164th Depot Brigade, the corresponding outbreak of pneumonia was almost exclusively in the same organization.

The epidemic of influenza first attacked the organizations which had been at Camp Funston during six months or more. It seems to have infected all susceptible individuals and to have thus spent itself. Subsequent waves of influenza occurred when newly drafted men were brought into the camp in April and again in May. Table 14 shows that pneumonia, like influenza, during the primary epidemic of March, attacked in great part men resident several months in the camp; 83.1 per cent. of those attacked by influenza and 72.2 per cent. of those attacked by pneumonia had been in camp more than three months. The pneumonia of April, like the influenza which it followed, was in great part in men who had been in the camp a short time. Only 16.5 per cent. of those with influenza, and 18.2 per cent. of those with pneumonia, had been in the camp more than three months, whereas 70.2 per cent. with influenza and 59.6 per cent. with pneumonia had been in the camp less than one month.

TABLE 14.—LENGTH OF SERVICE OF PATIENTS WITH INFLUENZA, PNEUMONIA AND ACUTE BRONCHITIS

	Under 1 Month		1-3 Months		Over 3 Months		Total
	Cases	Per Cent.	Cases	Per Cent.	Cases	Per Cent.	Cases
Influenza:							
March	95	8.2	92	7.9	969	83.9	1,156
April	255	70.2	49	13.4	60	16.5	364
May	140	66.8	36	17.1	34	16.1	210
Pneumonia:							
March	37	15.5	29	12.2	172	72.2	238
April	59	59.6	22	22.2	18	18.2	99
May	27	29.3	44	47.8	21	22.8	92
Acute Bronchitis:							
March	29	14.8	32	16.3	135	68.9	196
April	31	27.8	26	31.7	25	30.5	82
May	38	33.9	45	40.2	29	25.9	112

In May the figures representing the duration of residence in camp of those with pneumonia do not show the same close agreement with the figures representing influenza that is exhibited by the corresponding figures for April. The majority of cases of influenza occurred during the first month in camp, whereas the majority of cases of pneumonia occurred in the period between one and three months after arrival in camp.

The records of the hospital indicate that the pneumonia which accompanied influenza was lobar pneumonia and not bronchopneumonia. During the prevalence of pneumonia following measles in November and December, 1917, 21.4 per cent. of the cases of measles pneumonia were classified as lobar, and 78.6 per cent. as bronchopneumonia. Deaths occurred in 45.3 per cent. of the cases. Table 15 shows the distribution of lobar and bronchopneumonia and the percentage of deaths in the months of March, April and May.

The relatively low mortality of this outbreak of lobar pneumonia is in contrast with the higher mortality of the bronchopneumonia of measles. It is not possible to state what micro-organisms were concerned in the production of the lobar pneumonia following influenza, but it seems improbable that it was the hemolytic streptococcus which produces the fatal bronchopneumonia of measles. It is noteworthy that the fatality of pneumonia diminished during the outbreaks of April and May.

TABLE 15.—PNEUMONIA IN MARCH, APRIL AND MAY

	Lobar Pneumonia		Bronchopneumonia		Mortality	
	No. Cases	Per Cent.	No. Cases	Per Cent.	No. Deaths	Per Cent.
March	223	93.7	15	6.3	48	20.2
April	92	92.9	7	7.1	16	16.2
May	90	97.9	2	2.1	13	14.1

SUMMARY

Pneumonia which has occurred at Camp Funston since the establishment of the camp may thus be classified:

1. Pneumonia of a relatively stationary camp population. It resembles the pneumonia of civil life, and

has been characterized by the presence of a predominant proportion of pneumococci of Types I and II during the period of our study.

2. Pneumonia of newly drafted colored men from Southern states. This has been of mild type, with a low rate of mortality and few complications. It has been associated during the period of our study with a high proportion of those types of pneumococci which occur in the mouths of healthy men. Pneumococci Type II have not been found; Type I has occurred in great part in one company of men. It is not improbable that the incidence of various types is dependent on exposure of susceptible men to those types which are disseminated when drafts have been recently assembled.

3. Pneumonia following influenza. In March an epidemic of influenza swept through Camp Funston and quickly spent itself, presumably by the infection of all susceptible men. In April there was a second wave of influenza and in May, a third, almost wholly limited to newly drafted men brought into the camp a short time before these outbreaks. Corresponding to each of these three outbreaks of influenza, there was a period of greatly increased incidence of pneumonia and bronchitis. These diseases, in many instances, were associated with influenza. They were prevalent in the organizations attacked by influenza, and maintained the same relation to the length of service of the men affected; that is, men who had been in the Army several months were attacked in the first outbreak, whereas the second and third outbreaks of pneumonia occurred in great part in newly drafted men. The pneumonia associated with influenza was in most instances lobar pneumonia, and was followed by a relatively low rate of mortality (from 14 to 20 per cent.). With the information available, it is not possible to draw a sharp line between (1) the pneumonia of the stable camp population, (2) the pneumonia of the newly drafted Southern troops, and (3) the pneumonia following influenza. It is possible that influenza, in a greater or less degree, also acts as a predisposing factor in the production of the first and second varieties.

4. Pneumonia with measles. In November and December, 1917, there was an outbreak of pneumonia accompanying measles. The disease was predominantly bronchopneumonia, and the rate of mortality was very high (45 per cent.).

Examination of the mouths of healthy men in the camp for pneumococci has shown types usually present in the mouth, namely, Atypical Type II and Types III and IV in 61.2 per cent. of those examined. Pneumococcus Type I has been found only twice—once in a company in which four cases of Type I pneumonia had occurred, and once in a man who a short time before the examination had been in the hospital with otitis media and tonsillitis.

During the period of our investigation, hemolytic streptococci had an insignificant part in the production of pneumonia and its complications. There have been 112 cases of measles, but no complications referable to hemolytic streptococci. Hemolytic streptococci have been found in the mouths of one in four or five healthy men in Camp Funston. Evidence obtained has suggested that hemolytic streptococci may disappear from the mouths of patients with the onset of measles; few carriers were found during the period of the rash, but later the incidence of hemolytic streptococci gradually increased, and finally reached that of healthy men in their own organizations.

Bacillus influenzae has been found in the mouths of 35.1 per cent. of the healthy men examined at Camp Funston. It has been found associated with pneumococci in eight of sixty-two cases of pneumonia. We have had no opportunity to study the bacteriology of influenza.

A small group of cases of bronchitis have been studied. In all that have been examined by appropriate methods, pneumococci Type IV or Atypical Type II have been found. Of thirteen cases, all but two harbored either *Streptococcus hemolyticus* (four instances) or *Bacillus influenzae* (seven instances).

Clinical Notes, Suggestions, and New Instruments

IODIN CONSERVATION: CAMP LEWIS METHOD

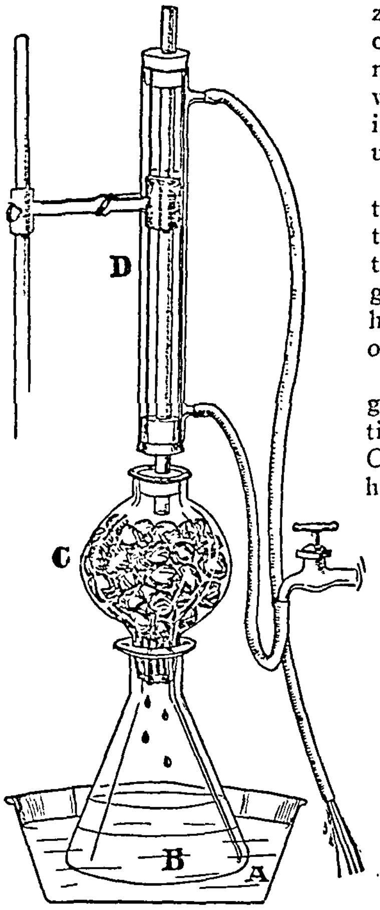
A. E. Rockey, M.D., (Portland, Ore.)
Major, M. C., U. S. Army
Camp Lewis, American Lake, Wash.

Tincture of iodin has by reason of its convenience and efficiency largely superseded other antiseptics for skin sterilization preparatory to surgical operations. The ordinary method is to paint the skin with a small gauze mop held in forceps. These mops are usually thrown away.

Long ago it occurred to me that the waste was greater than the use, and the saving of the mops was begun. The greatly increased cost of iodin has lately emphasized the need of conservation.

In collaboration with Sergeant Brown under the direction of Major Staniford in the Camp Lewis laboratory, we have worked out a practical method of conservation which we have now been using for several months.

The iodin mops are dropped into a conveniently placed dish in the surgery and are then saved in large glass jars. When they have accumulated in a sufficient quantity they are taken to the laboratory and the iodin is recovered in the form of tincture by repercolation with condensed alcohol vapor. The apparatus here illustrated is simple and may be obtained from any large dealer in chemical glassware.



Apparatus for recovering iodin from iodin mops: *A*, water bath; *B*, alcohol; *C*, iodin mops; *D*, condenser.

As the boiling point of alcohol is below that of water, it is only necessary to heat the water bath until the alcohol boils. The iodin does not volatilize from the liquid. A piece of moist starch paper placed at the open end of the condensation tube is not discolored. The condensed alcohol vapor drops back through the mops and carries the iodin with it in the form of tincture. It may be readily standardized by the color test, a convenient standard being a 1 dram vial filled with the desired percentage of the tincture. When desired, the residual dilution in the mops may be readily "squeezed" out by applying a cold, wet cloth to the upper portion of the alcohol flask. This may be done at the conclusion of the percolation, when the mops are white. They are then washed, resterilized and used again.

It is believed that the total waste of iodin in both military and civil hospitals enormously exceeds that which is actually utilized. It is suggested that groups of hospitals cooperate in the saving of their iodin mops and in the reclamation of both the iodin and the gauze.

At Camp Lewis we have requested civil hospitals in Tacoma, Portland and Seattle to aid us in demonstrating the utility of the plan by sending their mops to the base hospital laboratory.

REPORT OF A CASE OF EXTREME DISPLACEMENT OF THE VERMIFORM APPENDIX

George F. Straub, M.D., and G. C. Milnor, M.D., Honolulu, H. I.

The rarity of an extreme displacement of the appendix leads us to report this case, believing that it may be of interest and value to the profession.

REPORT OF CASE

History.—H. C., American laborer, aged 38, gave the history of having had indigestion and obstinate constipation for five years. During this period he also had felt nearly constant but mild pain in the right abdomen above McBurney's point. He had never had a typical attack of appendicitis, but said that often during his work and at night, a sudden sharp pulling pain would occur, always located about 2 inches above McBurney's point and radiating upward to the ensiform cartilage, where it would center for ten or fifteen minutes. He had lost 45 pounds in weight in five years and had been treated for various stomach disorders. Otherwise his history was negative.

April 15, 1918, the pain described above was so severe as to force him again to consult a physician. There was no fever. The pulse was normal. There was no vomiting and only slight tenderness a little above McBurney's point without any rigidity. The leukocyte count was 9,800. A diagnosis of chronic appendicitis was made and an operation advised.

Operation.—April 16, 1918, the patient was operated on at the Queen's Hospital, Honolulu. A McBurney incision was made, and after thirty minutes of careful searching the appendix was located. The cecum was found to be drawn upward about 3 inches out of position, while the transverse colon formed a rather long loop hanging down below the umbilicus, without omentum. It was this loop constantly appearing in the wound that led us astray in exactly locating the appendix. The base of the appendix was finally found 3½ inches above McBurney's point, not postcecal, but anterior and adherent to some organ above, pulling the cecum upward and dragging the ileocecal junction with it.

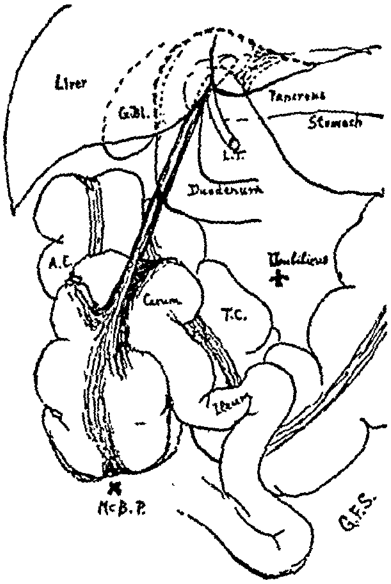
The accompanying illustration shows how the appendix in its course crossed part of the ascending colon, constricting it and also the beginning of the transverse colon, and then crossing the duodenum under the gallbladder passed underneath the pylorus ending on and adherent to the head of the pancreas.

As it was impossible to do anything more than locate the base of the appendix through the first opening, a high right rectus incision was made through which the tip was secured and freed from the underlying structures, a most difficult task, as the adhesions were very firm and numerous. Once loosened, the tip was brought out of the McBurney incision. The cecum then was able to occupy its normal position. From this point the appendix was tied off, amputated and the stump buried by purse-string. The appendix was 6 inches long, of normal thickness, and aside from two strictures (one of them near the tip) and a moderate degree of chronic congestion, did not present any abnormalities. There was no mesenteriolum.

The patient made an uneventful recovery and is now feeling perfectly well. He is free from pain. The indigestion and constipation have left him, and he is gaining weight right along.

PATHOLOGY

The pathology of this condition is most interesting. The appendix and cecum belong in the right lower quadrant of the abdomen. Any position outside of this location is to be classified as a displacement of the ileocecal apparatus. One group of such displacements may be caused by a long mesentery, a free and movable mesocolon, which is most frequently the case. We may call them floating ileocecum. The appendix may then be found in any location of the abdomen, occasionally in hernias, etc. The other group of cases have their foundation in arrested fetal development. Following up the embryonic genesis of the large intestine we see the primitive intestinal loop differentiate into the small and large intestine, and the beginning of the large intestine, the ileocecum, mainly due to the influence of the much faster growing small intestine, rotate over and around the latter, which process makes the ileocecal apparatus take a route over the spleen and stomach (eight weeks), duodenum (nine weeks), below the liver into the right hypochondrium (ten weeks) and from then on down toward its final and normal position (from the fourth to the seventh month). Kelly says that "the cecum may never reach the iliac fossa, if during its descent the ileocecal apparatus or any portion of it becomes adherent to neighboring organs, such as the kidney, the gallbladder or the duodenum." Consequently the fixation of the ileocecal apparatus may occur at any point while on its course during the embryonic rotation of the primary intestinal loop. According to statistics, the proportion of the undescended ceca in the male and female is about 2:1. It is also a fact that appendixes in such cases tend to retain the fetal type, that is, do not show the sharply defined border between cecum and appendix, although this was not the case in our observation.



Position of appendix, the tip of which was adherent to the pancreas, thus pulling the cecum upward.

If in the light of such knowledge we try to explain the pathology of our case, we must come to the conclusion that we have to deal with a displacement of the appendix, due to arrested fetal development, probably around the eighth week of embryonic life. From a clinical standpoint the symptoms were rather characteristic and interesting as compared with the operative findings.

401 South Beretania Street.

Surgical Instrument Manufacture in the United States.—The *Scientific American* summarizes from a recent report of the United States Tariff Commission information concerning the condition of surgical instrument manufacture in this country and shows our dependence on foreign instrument makers prior to 1914. In the latter year the value of all surgical instruments produced in the United States was $1,400,000, while the importations of steel instruments were valued at $1,500,000, about 95 per cent. of which came from Germany. It will be a surprise even to surgeons to know the great number of different instruments supplied. For instance, one of the largest importing houses offers to supply any one of 10,000 items, and well stocked retail dealers will carry from 6,000 to 7,500 different types. Heretofore the manufacture of surgical instruments involved a great variety of skilled hand labor. Since the beginning of the war standardized types of instruments have been produced in this country by machinery in place of hand work.

THE FUNCTIONS OF THE DUODENUM

The not infrequent necessity of surgical interference with the integrity of the alimentary tract inevitably raises the question as to the importance of such physiologic functions as may thereby be involved. In the case of the stomach there is now general accord with the view that this organ is not indispensable to life. Complete excisions have been made not only in experimental animals, but also in the human patient, without untoward results other than those necessitating a careful selection of diet because of the absence of preparatory digestive and bactericidal processes at the beginning of digestion. Surgical experience has demonstrated that varying lengths of the small intestine in the region of the jejunum and ileum can be removed without serious inconvenience. At most the ill effects of extensive resections of this portion of the intestine are represented by nutritional disturbances, the expression of incomplete digestion of an unsuitable diet. Truly systemic disorder is not a direct sequel to extirpations of this sort.

The removal of the duodenum presents far greater difficulties than those offered by the lower portions of the bowel. The intimate association of the pancreas with the duodenum, and the natural drainage of the stomach, the pancreatic and biliary ducts into this structure make the surgical problem more serious. But further than this there is the question as to the physiologic importance of the duodenum in whole or in part in relation to the maintenance of life. In other words, is the duodenum, aside from its digestive performances, necessary for life? On this highly important question the available evidence is most confusing. The long debated contention of the physiologist Pflüger that loss of the duodenum is certain to result in severe diabetes has been effectually disposed of as untenable by the consensus of competent experimenters. Nevertheless at least one American physiologist has maintained that the duodenum is as necessary to life as are the suprarenals or parathyroid structures, the implication being that it furnishes an indispensable hormone. To some degree the problem of duodenal function is involved in the controversies respecting the alleged toxemias of intestinal obstruction that have repeatedly been discussed in The Journal.[1]

The latest contribution on the subject, an experimental study at the State University of Iowa,[2] is somewhat reassuring, as the results are of a positive rather than a negative character. The report states that animals can survive indefinitely a complete extirpation of the combined jejunum and ileum. A dog was kept three months after a complete removal of the pyloric part of the stomach, the entire duodenum and the upper jejunum. Therefore the mucosa of this region of the digestive tract is not comparable to the suprarenals or parathyroids in function. Furthermore, the Iowa physiologists affirm, as the outcome of their observations, that the normal secretions of the duodenum and jejunum are not toxic. When bacteria are excluded from the lumen of the intestine, various pathologic changes, even to complete occlusion of the blood supply to an isolated piece of intestine with resulting autolysis and reabsorption, can take place without the elaboration of sufficient toxic substances in the cells themselves or in their secretions to kill the animal. The logic of the situation leads to the conclusion that the duodenum does not excrete in the duodenal juice any substance necessary for life or for the function of the intestine lower down. In other words, there is no evidence that the duodenal juice contains anything vitally necessary to the organism.

THE NATURE OF AUTOLYSIS

The softening or liquefaction of dead tissues without the intervention of bacterial putrefactive processes has long been recognized as a biologic possibility. In 1890, Salkowski announced that this postmortem self-digestion, or "autodigestion," as he termed it, is due to enzymatic changes of the sort subsequently designated as intracellular. The expression "autolysis" now in vogue to designate the same phenomena was introduced in 1900 by Jacoby. Since then it has gained increasing prominence in relation to various problems of chemical pathology. The importance assigned to the subject is indicated by the fact that some investigators have even regarded postmortem autolysis as a continuation of a normal intravital process; hence it was believed that a thorough understanding of the mechanism of autolysis might give a clue to the phenomena of protein changes in the living cell. As one writer[3] has expressed it, "It may be assumed with certainty that no one would have devoted so much effort and care to these rather bothersome subjects if it were not for the impression that just here there is a chance to remove one part of the intermediary metabolism from the dark interior of the living economy into the transparency of the test tube."

[2] Dragstedt, L. R.; Dragstedt, C. A.; McClintock, J. T., and Chase, C. S.: Extirpation of the Duodenum, Am. J. Physiol. 46: 584, 1918.

[3] Von Fürth, O.: Chemistry of Metabolism, translated by A. J. Smith, Philadelphia, J. B. Lippincott Company, 1916, p. 78.

The difficulty of reconciling the supposed behavior of the postulated autolysis enzymes of the various tissues, practically all of which have been shown to be capable of "self-digestion" or autolysis, with the manifestations of the familiar proteolytic digestive ferments has been considerable. Wells[4] concludes that the intracellular proteases assumed to be specifically responsible for autolysis are not altogether like either pepsin or trypsin; for they split proteins into the simplest compounds, whereas pepsin carries the digestion only to the peptone stage under ordinary conditions, and unlike trypsin their action is most marked in a faintly acid medium. To explain why agencies so potent for cell disintegration after death do not produce comparably profound dissolution of the tissues during life, various hypotheses have been advanced. The existence of specific antienzymes in the living cells as means of defense has been assumed. Again it has been suggested that the autolyzing enzymes are present only in the form of precursors or pro-enzymes which gain effectiveness under postmortem conditions. All recent workers have recognized the significance of the reaction of the medium in which the autolytic materials are present. In some cases the favorable acid, for example, has been believed to render the protein substrate more susceptible to digestion. In others the question of reaction has been interpreted solely with relation to the enzymes themselves. Despite all this confusion, volumes have been written on the presumable significance of autolysis in the disappearance of degenerated tissues, the softening of infarcts, the resolution of exudates, and related manifestations.

Recent studies of Dernby[5] at the Rockefeller Institute for Medical Research, New York, promise to clear up some of the obscurity surrounding the subject of autolytic enzymes. From this exceptionally well conducted investigation it seems likely that most, if not all, of the tissues—liver, spleen, pancreas, gastric mucosa and leukocytes were specifically investigated—contain proteolytic enzymes of the pepsin type and likewise of the trypsin or erepsin type. The latter demand a hydrogen ion concentration that is on the alkaline side, and have their action checked in a slightly acid solution. The pepsin-like enzymes, on the other hand, cannot act in alkaline or even neutral solution. According to Dernby, both types of proteolytic enzymes occur in all the tissues studied. In some of them, however, one or the other of the enzymes has been predominant over the others, as the pepsin in the stomach and the trypsin in the pancreas. Unlike the less specialized enzymes, pancreatic trypsin and gastric pepsin can easily be extracted from the cells.

Autolysis of tissues proceeds most rapidly and completely when the two types of enzymes can work simultaneously. This is in slightly acid solution. The optimal reaction lies between that for pepsin and for trypsin, respectively. Considering that there are enzymes in the tissues of both peptic and tryptic nature, says Dernby, and considering also the hydrogen ion concentration of the medium and its eventual changes, most of the autolytic reactions can be explained without assumption of hypothetic agents, such as "pro-enzymes," "activators" or "antienzymes." The significance of seemingly insignificant changes in reaction for the progress of many physiologic phenomena needs to be appreciated more than it has been. The modern study of hydrogen ion concentration in relation to biologic responses has brought to light many astounding and unexpected facts, among which these observations on tissue enzymes and their activities may now be classed.

"ASPIRIN"—A COMMON NAME

"Aspirin" as a trade-mark will no longer exist if the recommendation of the Examiner of Interferences of the United States Patent Office is upheld, as it probably would be, should the matter be taken to the courts. The opinion of the Patent Office was the result of a petition by the United Drug Company in the case of that company against the Bayer Company, or, as it was called at the time the suit was brought, the Farbenfabriken of Elberfeld Company. The stand taken by the Patent Office is directly in line with that that has been held in this and other cases by THE JOURNAL, which has for years insisted that it was against public policy to permit patentees to extend the seventeen-year monopoly, which the patent laws grant, to a perpetual monopoly by the simple device of obtaining a trademark for the name of the thing patented. It is a fundamental principle in law that "no one can have a monopoly in the name of anything." This of course has been recognized and admitted even by those manufacturers who have attempted to invoke the trade-mark laws to obtain an unwarranted advantage.

The manufacturers of aspirin have held that the chemical name "monoaceticacidester of salicylic acid" was the true name of the patented article, and was the *only* name which became public property when the patent right expired. The Patent Office points out, however, that for years the only name that the public ever saw on the brand of monoaceticacidester of salicylic acid made by the holders of the patent on this product was "Aspirin." The Examiner of Interferences in this decision points out that, previous to 1915, the Bayer Company sold no tablets to the retail-purchasing public, but marketed its product as a powder; further, that it did sell vast quantities of the powder to tablet-makers, who sold "Aspirin Tablets," and that the consuming public knew the product only by the name "Aspirin." This name, then, had a significance to the purchaser, similar to that of the word "quinin" on a package of quinin tablets, or the word "calomel" on a package of calomel tablets. As the Patent Office says: "In other words, the *prima facie* significance of this word 'Aspirin' to such purchasers was that of a name"—and as a name it is "necessarily incapable of exclusive use by any one."

[5] Dernby, K. G.: A Study on Autolysis of Animal Tissues, J. Biol. Chem. 35: 179, 1918.

The Patent Office's decision also brings out the fact that, until the owners of the aspirin patent commenced making tablets themselves, the aspirin tablets on the market were not uniform, and that this lack of uniformity was a fraud on the public which the owners of e aspirin patent should have prevented. The concern did prevent it when it began to make the tablets itself, but maintained in its contention against the United Drug Company that it was unable to control the matter previously—a contention to which the Patent Office gives short shrift. It is further pointed out that the Bayer Company evidently recognized the weakness of its contention by the emphasis it placed through its advertising on the "Bayer Cross."

When the Bayer Company began manufacturing its own aspirin tablets, it made a pretense of complying with the letter of the law, while violating its spirit, by placing on the label under the word "Aspirin," the statement that "the monoaceticacidester of salicylic acid in these tablets is the reliable Bayer manufacture. Says the Patent Office: "With regard to the expression 'monoaceticacidester of salicylic acid,' a mere inspection of it is sufficient to apprise any one of its inherent unsuitability for use as a name by the lay purchasing public." This attempt on the part of the company to "beat the devil around a stump" tended, in the opinion of the Patent Office decision, "to show that the respondent was familiar with the methods of some modern traders to meet the trend of the law." And, discussing such methods, the Examiner of Interferences says: "A very popular one is for a trader to seemingly bend to the necessity of the situation by placing on the label a notation which in theory, but not in practice, may be used by the public to identify the article after the monopoly has expired. To the examiner this practice seems to be merely a manifestation of that keen commercial instinct which endeavors to keep just ahead of the law. This instinct is fairly common in traders, and is clearly disclosed in trade-mark infringement cases."

Summed up, the decision is to the effect that, as in any case prior to 1915, the public had been driven to look on the word "Aspirin" as the name of a *thing*, and as the Bayer Company had not used the word as a "trade-mark" within the meaning of the law, the Patent Office recommends that the registration of "Aspirin" as a trade-mark be canceled. If no appeal is taken from this decision, or in case an appeal is taken, should the opinion be sustained, the attempt on the part of the patentees of aspirin to get a perpetual monopoly on their product through the trade-mark laws will have been definitely defeated.

THE MECHANISM OF EXPERIMENTAL PITUITARY DIURESIS

The investigation of the functions of the pituitary body, or hypophysis, and likewise the possibilities of the use of the gland in organotherapy have been complicated by the now recognized fact that the anterior and the posterior or infundibular portions exert unlike effects. The therapeutic applications have been restricted thus far to the study of the posterior lobe, with which is included the pars intermedia. Schäfer demonstrated several years ago that extracts of this produce a rise of blood pressure and diuresis. The intelligent employment of diuretics will depend, when therapy becomes rationalized, on a correct understanding of the mechanism by which each drug acts. In the case of the kidney the possibilities are at least twofold. Substances may provoke an increased production of urine by altering the blood flow through the renal vessels. These dilate, while the blood vessels elsewhere are more or less constricted, and a diuretic effect ensues. Or, the renal cells may be stimulated directly by the substance investigated. In this way urea and caffein act as diuretics.

How uncertain the mode of action of pituitary extract as a diuretic appears is indicated by the conclusions of Hatcher and Wilbert[1] in "The Pharmacology of Useful Drugs," wherein it is stated that:

> The renal vessels dilate while the splanchnic vessels constrict, and this effect has been invoked to explain the well-known diuretic action of pituitary, but there is no reason to doubt that it also acts directly on the renal cells causing an increased secretion, both actions probably being concerned in the diuresis.

True cellular activity means metabolism, which assumes a need of oxygen. "There is no instance in which it can be proved that an organ increases its activity under physiological conditions without increasing its demand for oxygen." If pituitary extracts actually provoke an increased activity of the renal tissue, the kidneys will show an augmented consumption of oxygen. In the latest experimental studies by Knowlton and Silverman[2] at the Syracuse University College of Medicine, the oxygen consumption was used as a criterion without obtaining any evidence that pituitary extract stimulates the kidney cells. On the other hand, increased blood flow through the kidney was an invariable accompaniment of pituitary diuresis. Hence Knowlton and Silverman conclude that from the evidence at hand it seems possible to explain the diuretic action of pituitary extract entirely on the basis of the vascular changes and increased filtration pressure obtaining in the kidney. Such vascular effects would be in harmony with the other more familiar actions of extracts of the posterior lobe on involuntary muscle.

Current Comment

ANNUAL REPORT OF THE PUBLIC HEALTH SERVICE

The annual report of the Public Health Service covering the fiscal year ending June 30, 1918, is interesting and unique in showing the relation of the Public Health Service to the military and naval departments in time of war. The year 1918 was marked by two important pieces of legislation relative to the Public Health Service: first, an executive order, issued July 1, placing all civil public health activities carried on by any federal executive department or agencies especially created for or concerned in the prosecution of the war, in the charge of this department, and second, the passing, October 27, of an act to establish in the Public Health Service a sanitary research corps. During the year the service carried out all of its usual work; controlled the sanitation of extracantonment zones; gave attention to industrial hygiene and the care of munitions plants and other factories making war materials; controlled the manufacture of biologic products, and, in cooperation with the Federal Trade Commission, assumed supervision over the manufacture of arsphenamin. All of this work is described in detail in the report. Sections are devoted to domestic and interstate quarantine; to extracantonment zone sanitation; to maritime quarantine; to sanitary reports and statistics and to maritime hospitals and relief. In that portion of the report concerning personnel and accounts, it is indicated that thirteen officers have been continuously detailed to the Navy during the war and that two officers are now on duty with the Army. Aid has also been extended to the bureaus of War Risk Insurance, the Emergency War Risk Corporation and the Federal Board for Vocational Education. At the close of the year the commissioned officers of the Medical Corps of the Public Health Service consisted of the Surgeon-General, one assistant surgeon-general, sixteen senior surgeons, seventy surgeons, sixty-one passed assistant surgeons and sixty-three assistant surgeons. The section devoted to publications shows that a great many reports have been published during the year covering many phases of research and investigation. In a final section on the needs of the service, Surgeon-General Blue urges the completion of the national quarantine system by acquiring the Baltimore and New York quarantine functions. It is also recommended that the national quarantine stations at the ports of Norfolk, Mobile, New Orleans and San Francisco be relocated as soon as possible. These stations are at present almost inaccessible to the cities that they represent. Additional funds are asked for the continuation and expansion of rural sanitation studies and for studies of industrial workers and plants and for research on diseases of unknown etiology. It is recommended that the relief work of the service be extended to include the care and treatment of civil employees when ill, and also that hospital accommodation be supplied for the treatment of discharged soldiers and seamen. The need of still further bettering methods of securing statistics is emphasized and, finally, additional appropriations are asked so that service literature may have wider distribution. The report of the Surgeon-General of the Public Health Service is a more personal report than that of either the Surgeon-General of the Army or of the Navy, since the names of officers engaged in various duties are given as well as the stations that they have occupied.

THE PHYSICIAN AND THE INCOME TAX

The present federal income tax law, however unpopular it may be, bids fair to improve the business methods of physicians, and to throw a light on the question of the doctor's income. It is too common for a physician to regard his cash receipts as his income. A physician when asked how he is getting along will say, "I took in $6,000 last year," or "I did $10,000 worth of business." Practices are advertised for sale on the same basis. Yet this is not the true income any more than are the gross receipts of a grocer or a dry-goods merchant. Any business man who regarded his total cash intake for the year as his income would be considered by his business associates as headed for the bankruptcy court or the lunatic asylum. The business man knows that out of his gross receipts must come his operating expenses, insurance, depreciation, replacement of stock, and interest on investment before he can even begin to estimate his profit for his year's work. Yet prior to the passage of the present law, the great majority of physicians would have been unable to estimate their income on any other basis. Few physicians, except city specialists with offices separate from their homes, have been in the habit of separating their business from their family and personal expenses. The income tax law has made it not only necessary, but also highly profitable for us to keep books more carefully than we have heretofore done, since exemption is allowed for all *legitimate* professional operating expenses. This calls for definite figures as to the amount spent for office rent, attendants and maintenance, drugs and surgical dressings, maintenance of automobile or other conveyance, medical periodicals, associations and meetings, etc. In a word, it requires us to estimate the cost of carrying on our business, and the difference between this and the gross receipts. Many physicians who have heretofore been entirely ignorant of what their business was costing them have been surprised to learn that their real professional income was one-third or one-fourth what they had supposed. The income tax, in its present form at least, is a war measure, and few, if any, will regret its disappearance or material *modification*; yet if during the time that it is in force we learn to keep systematic records of receipts and expenditures, it will have taught a most important lesson.

A REMARKABLE LETTER

At a recent meeting of the New Jersey Sanitary Association, the retiring president, Mr. G. W. Fuller of New York, read a letter addressed to him in January, 1892, by the eminent German sanitary engineer, C. Piefke, whose name is especially familiar to all those interested in the sand filtration of water supplies. Part of the letter as presented by Mr. Fuller[1] is as follows:

> Here in Germany, conditions have changed to be very uncomfortable. Militarism and bureaucracy are spreading over our very existence, and despite all effort, no success rewards him who does not occupy a high rank within this hierarchy. Then comes the unfortunate passion for titles among Germans in general, so that an individual is not esteemed according to his personal worth, but his social position. . . . America is today the only civilized country where no restraint is placed on the pleasure of working, either through antiquated regulations or through the rights of privileged classes.

Mr. Fuller goes on to say:

> The latter years of Piefke's life were spent very unhappily—deprived of his water-works position in Berlin and assigned practically to be a recorder of ground water statistics for the Berlin district.

The picture presented in Piefke's letter of German professional life twenty-five years before the war is a significant one. It is especially interesting in the light of what has happened during the last four and a half years.

GASTRIC SECRETION AND AMMONIA EXCRETION

It is more than forty years since Walter[2] demonstrated that the ammonia output in the urine can be increased or decreased by the ingestion of acids or alkalis, respectively. Recently we concluded[3] that there is no reason today for believing otherwise than that the sole function of the ammonia found in the urine lies in the neutralization of acids arising in the normal metabolic processes, assuming, of course, that acid is not fed as such. An interesting illustration of the phenomenon of ammonia production and excretion in relation to the gastric secretion of hydrochloric acid has just been pointed out by Ivy[4] in the Hull Physiological Laboratory of the University of Chicago. He has found that during gastric stimulation by food and by water, followed by absorption in the intestine, there is an increase in urinary ammonia. The degree of increase depends on the rate of absorption of the acid chyme. It is not enough that hydrochloric acid shall be secreted. Unless there is a subsequent absorption in the intestine, no alteration in the ammonia factor ensues. The ammonia excretion depends on the balance of acids and bases in the body. One might expect that when acid is abstracted from the blood for gastric secretion the blood would become alkaline; but it must be recalled that alkali is secreted in turn in the formation of pancreatic juice. If the acid is returned by absorption more rapidly than it can be neutralized by the intestinal alkali, it will be neutralized by the ammonia in order that the hydrogen-ion equilibrium may be maintained without drawing on the alkali reserve of the plasma, the importance of which we have frequently discussed.[5]

ANNUAL REGISTRATION OF PHYSICIANS, AND A DANGER

Much interest has been aroused recently in the plan to require an annual registration of physicians[6] which involves the annual renewal of the license and the payment of a nominal registration fee. The arguments advanced for this plan are sound and reasonable. Without such registration a physician presents his credentials, passes his examination, secures his license and begins to practice. Thereafter the licensing board has no authoritative means of securing information from him. He may remain in a single locality and continue as a reputable practitioner of medicine—and if this were always the case there would be no need of an annual registration. But he may move from one place to another in the same state, or he may secure licenses in several states and practice as an "itinerant quack," and the fact be unknown to any of the boards. Again, the physician may die, and it may even occur that one not educated in medicine will secure his diploma and practice under the name of the deceased physician, and the board have no direct means of discovering it. Several such instances have actually occurred. Under a law providing for an annual registration, properly administered, the state board would have reliable information regarding all of these irregularities. The board's records could be more accurate, since each practitioner would be required not only to state where he was practicing, but also to prove his identity by furnishing an affidavit containing other required data. Investigation of failures to send information would usually disclose deaths or removals, and the efforts to furnish identification would frequently, if not invariably, call attention to fraudulent practitioners. There is, however, a danger connected with the plan for an annual registration of physicians, and that is the possibility of a misuse of the additional funds in those states in which the boards divide among their members any surplus remaining at the end of the year. This should be avoided.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending Jan. 3, 1919, there were in the Medical Corps 28,222 officers, a decrease of 876 since the previous week. This personnel includes four major-generals, five brigadier-generals, 221 colonels, 2,449 majors, 9,209 captains and 15,814 lieutenants. There were in the active service 27,610, a decrease of 747 since the previous week. Discharges to date include 7,389 officers.

Medical Unit to Siberia

In connection with the announcement a few weeks ago of the formation of a medical unit for Siberia, we are informed that changed conditions have made it necessary to cancel the sending of this unit with the exception of five dentists, who are now en route.

Award for Bravery

Capt. James B. Clinton, M. C., U. S. Army, Philadelphia, assigned to duty with the British Expeditionary Forces in September, 1917, and with the 133d Field Ambulance, and was given the Military Cross on account of gallantry in action at Mount Kemmel, in May last, was awarded a bar to the Military Cross for gallantry in action, August 23.

Good Health of American Troops

An Associated Press dispatch from Chaumont, December 25, states that in the eight evacuation hospitals in the occupied area of the Third Army, there are only about 4,000 cases of illness, most of which are influenza. This amounts to less than 1.05 per cent. The Third Army has five hospitals in Coblenz, two at Treves and one at Mainz. Most of these were originally German hospitals, and have modern equipment.

Surg. FRIENCH SIMPSON, proceed to the Mobile Quarantine Station and assume temporary charge for a period of about one month.

Passed Asst. Surg. BAYLIS H. EARLE, relieved at Port Townsend, Wash., proceed to Portland, Ore., and assume charge of the Service at that port.

Asst. Surg. C. J. McDEVITT, relieved at San Francisco, Calif., proceed to Port Townsend, Wash., and assume charge of the quarantine service at that place.

Asst. Surg. B. E. ROBERTS, relieved from further duty in epidemiological work in connection with influenza and proceed to marine hospital, Stapleton, N. Y.

Acting Asst. Surgeons E. E. ADEL, S. B. BOWNE, H. R. CARROLL, MARION GLENN, W. P. S. HENRY, E. J. KEHOE and CORA A. MOON, directed to proceed to Harrisburg, Pa., for duty in connection with influenza control.

Acting Asst. Surg. W. S. Ritenour, relieved at Anniston, Ala., proceed to Raleigh, N. C., for duty in extracantonment sanitation.

Acting Asst. Surg. L. J. ZELLER, proceed to Harrisburg, Pa., for duty in connection with influenza control.

Asst. Epidem. W. K. SHARP, proceed to Centerville, Ala., to investigate a reported outbreak of smallpox.

Tech. Asst. A. SEIDELL, proceed to Boston, Mass., in connection with development of poisonous gases.

Scien. Asst. I. B. KRAUSE, proceed to Philadelphia, Pa., for duty with the Emergency Fleet Corporation in connection with the sanitation of shipyards.

Scien. Asst. TOM PAISLEY, proceed to Hope, Ark., for survey concerning influenza control and methods for the control of malaria.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Camp Grant as Reconstruction Post.—January 2, it was announced that Camp Grant has been selected among the eighteen cantonments designated as locations for reconstruction hospitals for the education and curative treatment of convalescent soldiers. Capt. Rouel H. Sylvester, U. S. Army, has been named as educational director for the new project.

Tuberculosis Offices Consolidated.—The Chicago and Springfield offices of the Illinois Tuberculosis Association will be consolidated immediately and operated in Springfield in the future. It is said that forty counties of Illinois have already taken advantage of the tuberculosis act which authorizes a county to establish and maintain a sanatorium for the care of patients suffering from tuberculosis.

Survey of Itinerant Physicians.—The director of the State Department of Registration and Education has addressed a letter to the secretary of each county medical society in the state asking information regarding the activities of traveling physicians who operate in the state of Illinois. The information desired is: (1) the names; (2) samples of advertising material used; (3) itineraries announced; (4) home addresses of itinerant physicians, and (5) information regarding citizens who may have fared ill at the hands of such practitioners.

New County Officers.—At the annual meeting of the Kankakee County Medical Society held in Kankakee, December 19, Dr. Eugene Cohn, superintendent of the Kankakee State Hospital, was elected president; Dr. Daniel J. O'Loughlin, vice president, and Dr. James T. Rooks was reelected secretary-treasurer, all of Kankakee.——At the annual meeting of the Adams County Medical Society held in Quincy, December 11, Dr. Adelbert M. Austin, Mendon, was elected president; Drs. Henry P. Beirne and Earl L. Caddick were elected vice presidents; Dr. Elizabeth B. Ball was reelected secretary, and Dr. Charles E. Ericson was elected treasurer, all of Quincy.

Illegal Practitioners Convicted.—Two illegal practitioners of medicine, Charles J. Brutus and F. W. Lensemeyer, were convicted in the county court of Champaign County, recently, for violating the Medical Practice Act through action taken by the Department of Registration and Education of the State of Illinois. Brutus is an old offender, but Lensemeyer is a newcomer, having come to Illinois from Michigan about a year ago. Both cases were bitterly contested. Mr. Morris of the firm of Morris and Hartwell of LaCrosse, Wis., general attorneys for the National Association of Chiropractors, and two local attorneys represented the defendants. Hon. Louis A. Busch, state's attorney of Champaign County, conducted the prosecution for the state and is said to deserve great credit for the able manner in which he handled the cases. Regular motions for new trials were made by the defendants. If the motions are denied, the amount of the fines to be imposed on Brutus and Lensemeyer will be announced by the court.

Chicago

Held for Selling Habit-Forming Drugs.—Dr. Edmond D. Converse was arrested, December 30, after having, it is alleged, pleaded guilty to the sale of 600 grains of heroin to a young man and woman at his office.

Personal.—Dr. Frank Smithies has been appointed medical consultant to the United States Marine Hospital at the port of Chicago, by the Surgeon-General of the U. S. P. H. S.——Dr. Walter S. Haines has been appointed a state food standard officer.

Report on the Influenza Epidemic.—The entire staff of the department of health of the city has collaborated in a complete report of the 1918 epidemic of influenza in a pamphlet of 110 pages. As far as the city was concerned, the epidemic began to show itself in the death returns, September 21, reached its height, October 17, and gradually declined until for the week ending November 23, the death rate had again reached 16 per thousand of population, which is about the normal rate. From September 21 to November 16, there were reported 37,921 cases of influenza and 13,109 cases of pneumonia, a total of 51,030 cases. The report details the efforts of the department in cooperation with the state and national health departments and the citizens in combating the epidemic, and in charts, tables and text analyzes the figures from all aspects—age, sex, civil state, nationality, etc.—and gives for comparison figures and other information in regard to the epidemic in other cities and in the Army camps. The pamphlet makes an interesting permanent record of the great epidemic, which has not yet entirely subsided, but shows still its effects in the sickness and mortality rates through recrudescences, from time to time, of greater or less extent.

INDIANA

Tuberculous Clinics to Be Established.—At a recent meeting of representatives of the city board of health, Chamber of Commerce and the Marion County Society for the Prevention of Tuberculosis, Indianapolis, it was suggested that a chain of tuberculosis clinics should be established in Indianapolis, that a permanent hospital for advanced cases of tuberculosis, both in white and colored people, should be provided as a supplement to Sunnyside Sanatorium, and that steps should be taken at once to battle against the rapid inroads of the disease.——The citizens of Lake County have voted in favor of the expenditure of $100,000 for the erection of a tuberculosis hospital. This hospital will also be open to returned soldiers.

Personal.—Dr. Hugh D. Wood, Angola, is reported to be critically ill.——Dr. Lewis L. Williams has been appointed city health commissioner of Brazil.——Dr. Thomas W. Moorhead, Terre Haute, has declined a position on the city board of health offered him by the mayor.——In the case of Dr. Nelson B. Ross, Muncie, who served nine months in the state penitentiary for murder, and who sought clemency, the state department has continued the case.——Dr. A. W. Tobias, Elwood, charged with assault and battery is said to have been assessed a fine of $100 and to have been sentenced to imprisonment for six months on the Penal Farm. The latter part of the sentence was, however, suspended and the prisoner paroled.

Sanatorium Notes.—The Antituberculosis Society of Noble County is negotiating with similar societies of Allen and DeKalb counties with a view of obtaining a joint hospital for the treatment of tuberculosis.——The Vanderburg County Council has decided that it cannot at present accept the Boehne Hospital, Evansville, as a county institution. It is voted, however, that in realization of the value of the institution, $10,000 be appropriated to meet its current expenses until the beginning of the year. It is also decided that, beginning January 1, an appropriation of $2,000 per month will be paid to the Vanderburg County Antituberculosis Society for the maintenance of the institution. This will provide a fund of $25,500 for maintenance during 1919.

MAINE

Survey of Lewiston and Auburn.—The state department of health has caused to be made health surveys of Lewiston and Auburn, and an analysis of the local health organization and administration, and recommends a number of things for the improvement of the service in both places. Both cities have part time boards of health composed of men not versed in sanitary science and are without expert advisers in such matters. The administration of public health work in these places is therefore said to be inefficient, wasteful, and does not obtain satisfactory results. The sanitary problems of the two cities are identical and they may be classed as one, and the following personnel for a modern health department for both is recommended: one expert health officer, one full time bacteriologist, two sanitary inspectors, three public health nurses and a clerk. Such a department would cost to maintain approximately $17,000. A number of recommendations are made with reference to milk and food inspection, school inspection, vital statistics, waste disposal and the sewerage of both cities on a definite plan, etc.

MARYLAND

Venereal Detention House to Be Established.—The state health department is perfecting plans for the establishment in the immediate future of a house of detention where persons affected with venereal disease may be placed for observation and treatment. At present there are two clinics in Baltimore, one at the dispensary of Mercy Hospital and the other at the dispensary of Johns Hopkins Hospital.

Personal.—Brig.-Gen. William S. Thayer, M. C., U. S. Army, who has been serving in France, will, on his return to this country within the next two weeks, resume his duties as professor of medicine of the Johns Hopkins Medical School. Dr. Thayer will take the place of Dr. Theodore C. Janeway, who died several months ago while serving on the staff of the Surgeon-General.——Dr. B. Holly Smith, Baltimore, has been reelected president of the State Game and Fish Protective Association.——Dr. Arthur G. Barrett, Baltimore, has been appointed chief medical examiner of the State Industrial Accident Commission, to succeed Major Robert P. Bay, who has resigned to enter the military service.

Influenza Increasing in Frederick County.—A recrudescence of influenza has become acute in some sections of Frederick County. The localities where the disease is worse are Walkersville, Urbabam and Rocky Ridge. Dr. William E. Todd, Hagerstown, sent by the state board of health, is assisting Dr. Joseph W. Long at Walkersville, and Dr. John D. Nichodemus, Walkersville, who relinquished his practice and retired several years ago, is also helping to fight the disease. Health Officer Dr. T. Clyde Routson, Buckeystown, stated that while many cases are scattered over the country, there was no reason for alarm, but abundant reason to use every precaution against the spread of the epidemic. He has advised against church funerals in cases of death from influenza. A request has been made to the state board of health for a physician at Urbana.

U. S. General Hospital No. 7 to Be Enlarged.—Plans are under way to erect five new buildings and to enlarge to twice its present capacity United States General Hospital No. 7, which is at Evergreen Junior, the residence in Guilford loaned the government by Mrs. T. Harrison Garrett as a recuperation center for blinded American soldiers. Evergreen Junior is not merely a hospital. It is an institution where men who have been suddenly plunged into blindness and despair are physically and mentally rehabilitated for civil life. Follow-up work is carried on, the soldier being followed into civil life and his surroundings arranged in a way calculated to insure his success. Lieut.-Col. James Bordley has general supervision of the work being done at the hospital assisted by Major Nicholas I. Ardan, M. C., commanding officer of the medical and military staff; Charles F. F. Campbell, director of the Red Cross Institute Building, and Harold Molter, educational director.

MASSACHUSETTS

Housing Service Created.—Health Commissioner Woodward of Boston announces that a group of sanitary inspectors in the service of the health department has been detailed for the more efficient and economical execution of the housing laws that are enforcable by the health department. The city at present is divided into twenty-nine districts, and a sanitary inspector is assigned to each who is to be responsible for the enforcement within his district of all statutes, regulations and orders pertaining to sanitation, the housing regulations being only incidental to his work. Under the proposed plan a larger district will be assigned to each inspector, who is to look after only housing conditions. The housing service will have to do particularly with the location, plan, structural condition and number of occupants of buildings so far as these features affect the health of the occupants, and a program of work will be laid down to correct as rapidly as possible objectionable housing conditions. The work will tend to define the needs of the city as to additional housing legislation.

MINNESOTA

Personal.—Dr. Cornelius Williams, St. Paul, is reported to be critically ill in St. Luke's Hospital with septicemia.——Dr. Ignatius J. Murphy, St. Paul, for five years field secretary of the Minnesota Public Health Association, and editor of the *Minnesota Health Journal,* has located at Aitkin.

Red River Valley Physicians Meet.—The quarterly meeting of the Red River Valley Medical Society was held in Crookston, December 27. Influenza was the chief subject of discussion. Dr. Franklin M. Dryden, Crookston, was elected president, Dr. Olaf Ed. Bratrud, Warren, secretary, and Dr. Arthur A. Kahala, Crookston, treasurer.

Southern Minnesota Association to Meet.—The annual meeting of the Southern Minnesota Medical Association will be held in Mankato, January 20 and 21, under the presidency of Dr. Melvin S. Henderson, Rochester. The annual banquet will be held on the evening of the first day and on this occasion the presidential address will be delivered, on "Fractures Considered as Potential Deformities." Dr. William J. Mayo, Rochester, will speak on "Some of the Hospitals in London with Special Reference to the Surgical Treatment of Fistula-in-ano as Perfected at St. Mark's." The annual business meeting will be held on the morning of the second day and will be immediately followed by the scientific program.

NEW YORK

New Hospital Recommended for West Point.—Col. William H. Haskin, M.D., U. S. Army, at a hearing before the House Military Affairs Committee, December 31, recommended that $465,000 be appropriated for a new hospital at West Point.

Personal.—In the suits brought against Dr. Corden T. Graham, Rochester, by Mr. and Mrs. Giuseppe De Prima, for damages said to have been sustained from roentgen-ray burns while undergoing examination, decision is said to have been filed affirming judgments for $2,000 and $1,000, respectively, against the defendant.——Dr. William H. Murray, Albany, has been reappointed postmaster of Albany for a period of four years.——Dr. Frederick R. Smith, Rochester, has been elected president of the New York Motor Federation convention.

New Officers.—The following officers of county medical societies have recently been elected:

Erie County: president, Dr. James E. King; vice presidents, Drs. Earl P. Lothrop and Arthur G. Bennett; secretary, Dr. Franklin C. Gram (reelected for the twenty-fifth consecutive term), and treasurer, Dr. Albert T. Lytle, all of Buffalo.

Albany County: president, Dr. Charles H. Moore, Albany; vice president, Dr. William B. Sabin, Watervliet; secretary, Dr. Percival W. Harrig, Albany, and treasurer, Dr. Joseph A. Cox, Albany.

Rensselear County: president, Dr. Christopher J. Patterson; vice president, Dr. William J. Fleming; secretary, William Quirk, Jr., and treasurer, Dr. Russell F. Benson, all of Troy.

Utica Medical Library Association: president, Dr. Harry T. Remmer, Utica; vice president, Dr. William O. Weiskotten; secretary, Dr. John Gromann; treasurer, Dr. Arthur M. Johnston, and librarian, Dr. Frederick T. Owens.

New Governor on Public Health Measures.—In his inaugural address, Gov. Alfred E. Smith clearly defined his policy in reference to social and health legislation. He recommends the passage of legislation to lift labor out of the category of commodities or articles of commerce and urges legislation that will afford adequate protection to women and children. He recommends the establishment of a minimal wage commission who shall serve without compensation and who shall have the power to fix the living wage to be paid to women and minors. He recommends that the compensation law be amended in keeping with the constitutional provision, to the end that occupational diseases and injuries may be subject to its provisions. Governor Smith strongly urges the enactment of a health insurance law, which he believes will result in greater precautions being taken to prevent illness and disease, and to eliminate the consequent waste to the state therefrom. He believes also that proper provision should be made for maternity insurance and points out that other countries are far ahead of us in this respect.

New York City

Harvey Society Lecture.—The second lecture of the current series of the Harvey Society Lectures, to be delivered, January 11, at the New York Academy of Medicine, is by Col. Eugene R. Whitmore, M. C., U. S. Army, on "Infectious Diseases in the Army."

Personal.—The report in the issue of December 21, that Dr. Sigmund Pollitzer had sustained a fracture of the skull in an automobile accident, was incorrect. Dr. Pollitzer states that he was in an accident and received a severe concussion of the brain, and was taken unconscious to the hospital, but did not have a fracture of the skull, and reported for duty three days after the accident.——Dr. Saul J. Selkin and Isaac Glassman were slashed with a razor by an insane patient, December 25.

Slight Recrudescence of Influenza.—The number of new cases of influenza reported to the health department has increased considerably during the week ending January 4, there being about double the number of cases reported for that date as compared with the daily average of the past four weeks. Health Commissioner Copeland had prophesied that there would be an increase in influenza and pneumonia following the arrival of the United States Navy and the attendant celebration, owing to the conditions of crowding and exposure that inevitably accompany such an occasion.

New Officers.—At the annual meeting of the Medical Society of the County of Kings, December 17, Dr. Stephen H. Lutz was elected president; Drs. Robert L. Moorhead and John A. Lee, vice presidents; Dr. Charles E. Scofield, secretary, and Dr. Alfred Bell, treasurer, all of Brooklyn.——At the annual meeting of the Queens-Nassau County Medical Society, December 17, Dr. L. Howard Moss, Richmond Hill, was elected president; Dr. Arthur D. Jaques, Lynbrook, was elected vice president, and Dr. James S. Cooley, Mineola, secretary-treasurer for many years, was reelected.——At the annual meeting of the Richmond County Medical Society, Dr. John D. Lucey was elected president; Dr. Daniel P. MacGuire, vice president; Dr. John S. Ware, secretary, and Dr. Edward D. Wisely, treasurer, all of Staten Island.

Annual Reports of New York Academy of Medicine.—At the stated meeting of the New York Academy of Medicine, January 2, Dr. Walter B. James, who has been president for four years, retired and Dr. George David Stewart assumed the duties of the office. The annual reports of officers, committees, etc., for the year 1918 were presented. The report of the president showed that in spite of the war conditions the usual activities of the academy had gone on without interruption. An attendance at the meetings that was quite equal to that of other years testified to a growing interest in them on the part of the medical public. The project for building a fireproof addition to the building on the adjoining lot has necessarily been held in abeyance during the war. The plans, however, have been drawn and are now being completed in detail. In spite of the fact that members absent in the national service have largely availed themselves of the opportunity of having their dues remitted and of certain unusual expenses, the academy has been able to continue its activities throughout the year without a deficit. The Academy Extension Fund is not quite adequate to build and equip the proposed new structure and it is hoped that Fellows will subscribe sufficient additional funds to make this possible.

OHIO

Academies Elect Officers.—At the annual meeting of the Columbus Academy of Medicine, December 20, Dr. John H. J. Upham was elected president, Dr. William F. Whitten, vice president, and Dr. James A. Beer, secretary-treasurer.——At the annual meeting of the Cleveland Academy of Medicine, Dr. Frank Oakley was elected president, and Dr. Jacob E. Tuckerman, vice president.

Personal.—Dr. Thurman R. Fletcher, Columbus, Vinton County, has been appointed chief medical examiner of the State Industrial Commission.——Dr. Frank H. Lord, assistant physician of the Oxford Retreat, has resigned and taken charge of a sanatorium near Dayton.——Dr. Hugh H. Dorr, Grove City, fourth assistant medical examiner, has been promoted to first assistant medical examiner of the State Industrial Commission.——Dr. Guy H. Williams, Columbus, for fifteen years physician and assistant superintendent of the Columbus State Hospital, has been appointed superintendent of the Cleveland State Hospital where he has been acting superintendent.——Dr. George W. Martin, Portsmouth, who has been critically ill with pneumonia, is reported to be improving.——Drs. George H. Schomaker, Cincinnati, Mark E. Bowles, Charles A. Stammel, and Estella M. R. Caldwell have qualified for permanent appointment as district physicians of the health department.

OKLAHOMA

Personal.—Capt. Henry D. Shankle, M. C., U. S. Army, Oklahoma City, sustained serious injuries, November 19, by the overturning of his automobile.

Advocates Sanatoriums.—Dr. John W. Duke, Guthrie, state health commissioner, has endorsed the plan of establishing sanatoriums for tuberculosis patients in Oklahoma.

New Officers.—At the annual meeting of the Pontotoc County Medical Society the following officers were elected: president, Dr. Leander M. Overton, Fitzhugh; vice president, Dr. Bedford F. Sullivan, Ada, and secretary-treasurer, Dr. Samuel P. Ross, Ada.

PENNSYLVANIA

Cited for Bravery.—Miss Cora S. Moyer, Fleetwood, a nurse in the American Army overseas, has been cited for bravery under fire by General Pershing.

Personal.—Dr. Edward F. White, Reading, has been appointed resident physician at the Hamburg Sanatorium.——Dr. Carl H. Metzger, Altoona, has been reappointed police surgeon and medical member of the Civil Service Examining Board of Altoona, to succeed Dr. Louis E. McKee, who has resigned.——Dr. Jacob I. Roe has been elected president and Dr. Peter P. Mayock, secretary of the Medical Advisory Board of Wilkes-Barre Contagious Disease Hospital.

Philadelphia

Public Health Service Work.—At the meeting of the College of Physicians, December 27, Senior Surgeon Charles E. Banks, U. S. P. H. S., Washington, D. C., read a paper entitled, "Reconstruction Program of the Public Health Service."

Personal.—Major Charles H. Frazier, who was commissioned a major at the beginning of the war in the Medical Corps in the Army and who was attached to the Cape May Hospital as chief of the surgical division, has been appointed general consultant in neurologic surgery to the Surgeon-General of the Army.——Dr. George E. deSchweinitz has been appointed general consultant in ophthalmologic surgery to the Surgeon-General.——Dr. A. J. Ellis, associate professor of pathology in Jefferson Medical College, will go to Siam to organize the department of pathology in the Royal University at Bangkok.——Dr. H. C. Wood, Jr., is reported to be ill at the University Hospital with typhoid fever.——Dr. Dorothy Child, Germantown, has returned after several months' service with the pediatric unit in France.

GENERAL

New Member of National Board.—At a recent meeting of the National Board of Medical Examiners, Dr. William H. Welch, Baltimore, was elected a member of the board, succeeding Dr. Henry Sewall, Denver, resigned.

Western Surgeons Elect Officers.—At the twenty-eighth annual meeting of the Western Surgical Association, held in Chicago, December 21, the following officers were elected: Dr. Roland Hill, St. Louis, president; Drs. Emil G. Beck, Chicago, and George N. Kreider, Springfield, Ill., vice presidents; Dr. Arthur T. Mann, Minneapolis, secretary-treasurer, and Drs. Jabez N. Jackson, Kansas City, Mo.; Edward Evans, LaCrosse, Wis., and Edward S. Judd, Rochester, Minn., members of the executive council. The next meeting of the association will be held in Kansas City, Mo.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian, and Sloane Maternity hospitals, New York City, each $10,000; Post-Graduate, Manhattan Eye and Ear, Women's and St. Andrew's hospitals, New York City, each $5,000 by the will of James P. Steers.

French government institutions for blind and helpless, crippled soldiers, $96,500; Asylum of St. Vincent de Paul, Ecole maternelle, Paris, and the New York Hospital, each $3,820 by the will of Jean de Bourbis.

Philadelphia Home for Incurables, Women's Medical College of Pennsylvania, Women's Hospital, Charity Hospital, Philadelphia, and Norristown, Pa., Industrial Home for Blind Women, each $10,000 by the will of Mary H. Wood.

Associated Charities, Children's Free Hospital, and Marquette University, Milwaukee, each one third of the income accruing from $75,000 worth of stock in the Cudahy Company, by the will of Miss Helen Cudahy.

Staten Island Hospital, $5,000 by the will of Stacey Richmond.

FOREIGN

Deaths in the Profession Abroad.—Dr. **Rafael Rubirosa,** a graduate in medicine of the University of San Domingo, who had been taking postgraduate work in New York City; aged 32; died in the Manhattan State Hospital, December 6, from chronic endocarditis.

Nobel Prize in Physics.—This prize, for 1917, has been awarded by the Swedish Academy to Prof. C. G. Barkla, professor of natural philosophy in the University of Edinburgh, for his work on roentgen rays and secondary rays. The prize in physics for 1918, and that in chemistry for 1917 and 1918, have been reserved.

Medical Victims of Influenza in Spain.—The *Medicina Ibera* of Madrid states that 200 physicians have died from influenza during the recent epidemic of influenza in Spain. It cites a notice in the daily press to the effect that the authorities have appropriated a sum of money to be distributed among the widows and orphans of these medical victims of the epidemic. The sum appropriated is 2,000 pesetas; that is at the rate of 10 pesetas per family. A Spanish peseta is equivalent to the French franc, not quite 20 cents. Our exchange comments on this that the lack of organization and union among physicians is responsible for the profession being held in such slight esteem in political circles as is evidenced by this appropriation.

Spain Gives Traveling Scholarships.—The *Revista de medicina y cirugia prácticas* states that among this year's traveling scholarships recently announced by the official *Gaceta* at Madrid is one to Dr. J. Bosch, for a year's study at the University of Berne, Switzerland, on the physiology and pathology of nutrition. Another is for Dr. J. M. Riezgo, for six months' study of biologic chemistry at a Swiss university, and another for Dr. V. M. Nogueras, for six months' study of artificial appliances and reeducation of the maimed, in France and Switzerland. The other scholarships go to recent graduates, for six or eight months' study in France or Switzerland, of the effects of war wounds of the eyes, or the pathology of the endocrine system, or a year in Switzerland for study of the action of the radium and roentgen rays on the ovaries and gynecologic tumors.

Prizes Awarded by the French Académie de Médecine.—At the annual meeting, Dec. 10, 1918, the Académie de Médecine had fifty-seven prizes to distribute but, on account of the war, no competing articles had been presented for fifteen of the prizes and none deemed worthy of the prize for eleven others. The remaining thirty-one prizes were awarded to physicians of Paris or other French cities with the exception of one prize part of which was given to Messerli of Lausanne, Switzerland, for his systematic records of the physical measurements of Swiss soldiers. The Monbinne prize, given for the best report of a scientific mission, was divided between a French colonial medical officer and Dr. J. N. Roy, physician at the Hotel Dieu of Montreal, for his work on the eye affections in natives of Africa suffering from syphilis or trypanosomiasis. Honorable mention was accorded a work by a medical woman, Dr. Condat, on leukocytolysis. Honorable mention was also accorded a work on the changes in the bones in leprosy, by Dr. J. A. Honey of New Haven. The money prizes awarded ranged from 300 to 7,200 francs each. The Académie has held no elections during the war, but at this meeting it elected sixteen regular members to fill vacancies in the sections, and elected Clemenceau member at large, with M. Gross of Nancy as national associate member, and Dr. W. S. Thayer of Baltimore as foreign associate. During the year just closed, the Académie lost five regular members, including Pozzi and Gaucher; two national associate members, Ehrmann and Grasset; with four national corresponding members, including Régis, Maurel and Jeannel, and three foreign corresponding members, Istrati of Bucharest, Revilliod of Geneva, and Guareschi of Turin.

Influenza in South Africa.—Newspapers from Cape Town and Johannesburg, South Africa, covering the latter part of October describe the influenza situation as extremely serious. Although the proposal to close up all places of business was defeated at a special meeting of the Chamber of Commerce of Cape Town, yet the town was practically at a standstill as far as business was concerned and the streets were deserted. The number of cases of influenza was large and the deaths were so many that the bodies could not be taken care of. Many were collected on the beach awaiting burial. Physicians, nurses and volunteer aids were overworked, and many patients died without having any attention of any sort. Nurses would visit houses among the natives and perhaps find several dead with others ill, none of them having had any care. Everything possible was done by the authorities to relieve the situation. Vaccines were prepared and administered to the extent of the supply that could be manufactured. Depots or aid stations were established throughout the municipal area both at Cape Town and at Johannesburg, where the situation was about the same as at the former place. These were the headquarters for the efforts at controlling the situation in the different sections. The proportion of serious cases was large, and at Johannesburg the mortality was about 30 per cent. At one time forty-two of the nurses at the Johannesburg Hospital were ill, as also a number of the members of the staff of physicians. Dr. R. P. MacKenzie, superintendent of the hospital, speaking of the disease, said: "The majority of medical men in Johannesburg have seen nothing so terrible as the present epidemic. In 1890 Edinburgh was seized with an epidemic of Russian influenza, but it was a mere fleabite compared to what Johannesberg is going through today. We are not yet attacked with pneumonic plague, but I admit that clinically the symptoms of many victims are exactly the same as those of pneumonic plague; but we have not got the plague. Our slum areas and the poor condition of the unfortunates living in them have combined to give the disease such impetus as to assume plague proportions. Other cities and towns in South Africa also reported great prevalence of the disease."

MEXICO LETTER

Mexico City, Dec. 29, 1918.

Interchange of Professors

With the object of drawing closer the relations of a scientific character between both countries, the Department of Education of the Committee of Public Information of the City of New York has applied to the Mexican embassy at Washington suggesting the advantages of organizing a series of lectures on educational topics by United States professors coming to Mexico for the purpose, and by Mexican professors going to the United States, so that by this means the culture of the two republics would be diffused abroad to that extent. The proposition of the New York committee has been officially transmitted to the rector of the National University here, and it is hoped that he will regard the idea with favor and aid in its realization.

The Epidemic of Influenza

Information has been received to the effect that the epidemic of influenza is causing grave ravages in the states of Sonora and Sinaloa on the Pacific coast. The port of Mazatlan has been scourged worst by the disease. In the state of Chiapas the epidemic has subsided after having caused, it is estimated, 12,000 deaths.

The National Public Health Service

The Departamento de Salubridad has made arrangements to publish a supplement to its official *Boletin* which will appear more frequently than the latter, and will be devoted mainly to reporting the progress realized in the field of chemistry applied in pharmacology and pharmacy in Mexico. This branch of applied chemistry has developed considerably of late owing to the scarcity of drugs previously imported but shut off by the great war.

This same government service is now considering a drastic decree for combating alcoholism, which would materially restrict the manufacture and sale of intoxicating drinks.

Personal

Dr. C. Barajas, director of the Allied review, "Verdun," is seriously ill at present.

Dr. A. G. Figueroa has been appointed director of the National Library, the first establishment of the kind in the Republic.

Spanish Edition of the Journal

So far as I have been able to learn, the news of the early publication of a Spanish edition of The Journal has caused an altogether favorable impression among the physicians of Mexico. Numbers of persons have already subscribed for it. The Journal is much appreciated and read in Mexico, but as unfortunately the number of physicians who can read English is not very large, its circulation has been relatively small. This drawback will be obviated with its publication in Spanish, and it will contribute to mutual advantage toward extending and making more cordial the scientific relations between the physicians of the two neighboring countries.

School for Backward Children

The national school authorities having jurisdiction over the federal district and territories, have added this year to their budget—which is still awaiting the approval of the Chamber of Deputies—an additional 5,000,000 pesos. This is to cover the expense of truant officers, to ensure that all children of school age are attending some institution of learning, and also to found a school for backward and feebleminded children. There has been no provision for a school for these abnormal children before, and the lack of it has been much felt. The only special schools hitherto organized have been those for the blind, the deaf mutes and the children with ringworm.

Quackery in Mexico

With grave injury to the interests of the public, quackery in the city here is flourishing more and more every day as there is no legal restriction whatever to prevent any one that wishes to practice medicine from doing so. The quacks get clients among the ignorant by means of attractive and misleading advertisements in the daily papers. The favorite special fields chosen by these charlatans are syphilology and electrotherapy.

Medical Society

The Sociedad Medica del Hospital General has been recently reorganized. It comprises the medical force of this hospital but for some time the society had lapsed. Dr. Sepúlveda, director of the Beneficencia Publica, has taken the initiative in the resuscitation of the society.

Measures to Prevent Conception

The National Public Health Service, the Departamento de Salubridad, has published a decree prohibiting the sale and advertising of measures designed to prevent conception. The order is based on the grounds that this business is immoral and contrary to the interests of the public. The order is important because hitherto no check has been imposed on the speculators who make a business of manufacturing these so-called specifics, with which they defraud many foolish persons.

The Junta de Beneficencia Privada

This association was founded recently to cope with the epidemic of influenza and, since that need has passed, has continued its work in improving conditions as to hygiene in this city. It proposes to use the remainder of the sum realized by donations from private individuals (the sum to date totals 62,000 pesos), in founding public kitchens for the needy and securing shelter for the poor. The association has recently imported from the United States a quantity of drugs and has been dispensing them at cost price. They were obtained, thanks to facilities afforded by his Excellency, the United States ambassador, Mr. H. P. Fletcher. The president of this charitable Junta is Mr. C. B. Zetina, a progressive manufacturer, who at one time was president of the city council.

Examinations

The partial examinations in the medical school have just been completed, and the students in general made a good showing.

LONDON LETTER

London, Dec. 18, 1918.

The Influenza Epidemic

It has been estimated that in the whole world about 6,000,000 persons have died from influenza during the past twelve weeks. Not since the Black Death has such a plague swept over the world. In India some 3,000,000 deaths have occurred, of which there were 15,000 in Bombay. Delhi, with a population of only 200,000, had 800 deaths a day. In the Punjab, 250,000 persons perished. South Africa also suffered severely. In Cape Town, 2,000 children were left destitute as a result of the disease. Australia sent a ship to Samoa because the disease was affecting 80 per cent. of the natives. The white population could only feed the living and bury the dead. The epidemic seems to have begun in Spain last summer in a mild form with comparatively few deaths, and in that form spread across Europe, reaching London about June. It then spread to America; and while serious accounts were received from there, it had practically disappeared from London in August and September. In October, the second wave appeared with its high mortality from pneumonia, and it reached a climax in November. It slowly declined, and a few cases are still occurring in London.

The Prohibition of Gas Warfare

The presidents of the Royal Colleges of Physicians and Surgeons of England, Scotland and Ireland, Sir Clifford Allbutt, and Sir William Osler have published in the *Times* a joint letter suggesting that the use of poisonous gases in warfare be abolished at the forthcoming peace conference. They point out that their introduction by the Germans was a violation of the principles of morality which had hitherto exercised some control over civilized warfare, as well as a violation of the Hague Convention, to which Germany was a signatory. The Allies had in self defense to retaliate, but now that the need is over, fresh safeguards should be devised to prevent any nation from employing such methods again. They consider gas as condemned for the following reasons: It is an uncontrollable weapon, whose effects cannot be limited to combatants. It is an "unclean" weapon, condemning its victims to death by long-drawn-out torture. It opens the door to infinite possibilities of causing suffering and death, for its further development may well lead to the devising of an agent that will blot out towns, and even nations.

The Medical Examination of Aviators

In the medical examination of aviators it has been found that in some cases men of perfect physique, apparently quite unafflicted with nerves, absolutely failed to make even passable pilots. The discovery led to the formation of a special "medical flight" where such pilots have been able to work under medical supervision, the causes of their failure ascertained, and, wherever possible, remedied by special treatment. During the rough and tumble of 1914, the selection of successful pilots was necessarily a good deal a question of the survival of the fittest. After this stage a careful medical and physical investigation was made of the survivors of that gallant band of pilots who went out with the first five squadrons in 1914. This gave the preliminary data as to the necessary physical qualifications of a successful pilot, which now form the basis of the standard required by the present medical board for all aviation candidates. Later on, and as soon as the exigencies of war permitted, an investigation on similar lines was made as to the characteristic mentality of these pilots, and with the information thus collected the medical flight began its important work. One of the first qualifications required by a good pilot is alertness; this is tested by measuring the reaction time to an electric lamp suddenly switched on. The emotional element is also tested so as to ascertain whether fear has a stimulating or paralyzing effect.

The Profession after the War

In his address to the General Medical Council, the president, Sir Donald MacAlister, referred with pride to the great part performed by the profession at home and abroad in preserving the health of the forces and the people during the struggle. The strain on physicians in civil practice, already severe enough, has been increased by the prevalence of epidemic illness. There is good hope that this strain will speedily be relieved by the release of physicians from military service at the rate of some hundreds every month. The professional committees in Great Britain which, with the guidance of members of the council, have so effectively aided the government in recruiting for the medical services during the war, are cooperating with the authorities in solving the scarcely less difficult problems of demobilization and resettlement. In particular, it has been arranged that the release of teachers in medical schools and hospitals shall have special consideration. The influx of students returned from active service, with a view to the early completion of their professional course, makes it urgent that the sadly depleted staffs of skilled instructors should be reinforced without delay. The number of newly qualified physicians would this year be below the average, notwithstanding the steps taken to recall senior students from the Army to the medical schools. Somewhat tardy measures had been adopted to maintain the supply of senior dental students; but so far the qualified dentists added to the Dentists' Register had been few. The number attending the schools of dentistry with a view to qualification was also very small. The prospect of a considerable addition to the ranks of qualified dentists, plainly required to meet immediate wants, was not encouraging.

The Culminating Brutality

In all the black history of the German method of warfare, nothing has been viler than the reported treatment of sick prisoners. What it is to be hoped is the last example has come to light at Namur on the entry of the Allies. The diet of the sick prisoners there was 4 ounces of black bread a day with coffee in the morning and rice soup at noon, and a teaspoonful of jam every forty-eight hours. Every prisoner was emaciated and suffering from intestinal troubles brought on by the diet. When the Germans had to leave, they made no attempt to hand over the prisoners in hospital to any authority or representative of the Allies; they did not even inform the patients or the civilians that they were going. They merely went away and left the patients alone. There were about a dozen places used as hospitals, the existence of some being unknown to the civilians. These contained about 600 patients. Civilians penetrated into some the first day. At others patients remained absolutely unvisited for forty-eight hours, when, driven by hunger, some who could walk went out into the streets to seek food, and then only did the citizens hear of the situation. When they entered, they found an almost incredible state of affairs. In one institution, six patients lay dead in their beds. The condition of filth and the evidences of neglect were loathsome, the places being littered with dirty bandages and refuse of all sorts, so that the atmosphere was simply terrible. It was five days after the Germans had left the hospitals that the first British medical officers arrived, and ten days before there was anything like a proper supply of invalids' food and medical necessaries. Meanwhile, residents of the town did everything possible.

PARIS LETTER

Paris, Dec. 5, 1918.

Nervous Complications in Present Epidemic of Influenza

At a recent meeting of the Société de neurologie, Dr. G. Roussy called attention to the infrequency of complications of the central and peripheral nervous system during the present epidemic of influenza, even in those sections where the disease was of considerable severity and where, since the beginning of the summer, cases of this kind were sought with care. Only four such cases have been encountered: (1) A case of polyneuritis, of the motor type with paraplegia predominating, involving all four extremities, appearing on the fifth day of the disease. (2) A case of polyneuritis involving all four extremities, appearing during convalescence from influenza of the bronchopneumonic type. (3) A case of neuritis of the incomplete sensory-motor type involving the legs only, occurring during convalescence from a mild attack of influenza. (4) A case of apoplexy with left-sided hemiplegia occurring during the course of pulmonary influenza; at the present time, six months after its onset, the hemiplegia is gradually subsiding.

The findings obtained from lumbar puncture in these four cases are worthy of note. In each case there was hyperalbuminosis and a clear lymphocytosis; sometimes as many as 80 or 100 lymphocytes per field were seen, showing that the meninges were involved in the infectious process. Dr. Roussy stated that either he was particularly fortunate in not having a larger number of nervous system complications among his cases, or the nervous system was not specially exposed to involvement in this epidemic of influenza. Dr. Souques confirmed Dr. Roussy's observations as to the infrequency of this complication in the present epidemic. Among 400 cases observed by him there was not one case of this complication.

Dr. E. de Massary stated that a meningeal reaction consisting of a slight lymphocytosis occurs frequently in influenza even when there is no involvement of the nervous system.

Interallied Conference of Scientific Academies

The Conférence interalliée des Académies des sciences des pays de l'Entente has concluded its work. It was resolved to appoint an executive committee of five members whose function it shall be to study in detail the various questions discussed by the delegates to the conference. The committee consists of M. Emile Picard, permanent secretary of the Académie des Sciences of France, president; M. Schuster, secretary of the Royal Society of London, secretary; M. Hale, member of the Academy of Science of Washington; M. Lecointe, member of the Académie royale des Sciences of Belgium, and M. Vito Volterra, member of the Italian Académie royale des Lincei. It has been decided to establish several international scientific associations. Scientists of Germany, Austria-Hungary, Turkey and Bulgaria will be denied membership in them.

Demobilization of Medical Officers

Inasmuch as the university centers are endeavoring to resume their activity, all assistant professors and hospital physicians now in service will be returned to their faculties. Beginning January first, the medical officers will be recalled from the front according to the time spent with units in active service. On the other hand, physicians of all classes up to the class of 1894 (44 years of age) inclusive, (class of mobilization, and class fixed by the number of dependent children), will be returned to civil life and will continue to draw pay, thus enabling them to build up a practice. The physicians of the invaded regions will be returned to their place of residence at once, and means are now being devised to supply them with such instruments as they may require as part of their war indemnity.

Permanent American Red Cross Committee in Paris

The work undertaken by the American Red Cross in France is too important to be allowed to cease with the end of the war. Therefore, a permanent bureau will be established in Paris which will be under the direction of the parent organization in New York. It is the first branch established in continental Europe. The Paris bureau has full control of the work of the departments of the Seine and Seine-et-Oise. Major Gurney E. Newlin, who was president of the Los Angeles branch, is president and director of the Paris committee.

Clemenceau Sanatorium

Acting on the suggestion of M. Mesureur, directeur de l'Assistance publique, the conseil de surveillance for that department has decided to give to the tuberculosis sanatorium at Bicêtre, containing 400 beds, the name of Sanatorium Clemenceau in honor of the premier who was provisional intern in the hospice de Bicêtre in 1863.

Emergency Transportation for Physicians

In order to ensure immediate medical attendance for the sick during the prevailing epidemic of influenza, the Paris municipal council appropriated 50,000 francs to defray the expense of transportation of physicians by means of autotaxis for a period of two months. These twenty-six taxis will be available for service each night from 8 p. m. to 4 a. m.

Personal

The *Association générale des médecins de France* has elected the premier, M. Clemenceau, honorary president of the association. Such action has never before been taken by the association.

M. Clemenceau was also unanimously elected a member of the Académie de médecine, section des associés libres. M. Clemenceau presented his doctorate thesis on a histologic subject in 1865. He practiced medicine for several years, at Rochester, New York, and in Paris. [His medical career was outlined in The Journal, Dec. 8, 1917, p. 1976.]

Dr. Sieur, médecin inspecteur général de l'armée, was elected to membership in the Académie de médecine in the section on surgical pathology.

Marriages

Clayton Gregg Woodhull, Capt., M. C., U. S. Army, Decker, Mich., on duty at camp hospital, Air Service Depot, Morrison, Va., to Miss Winifred Susan Flaherty, C. N., U. S. Army, N. C., at Newport News, Va., December 21.

Jesse Hughes Maybry, Lieut., M. C., U. S. Army, Newport News, Va., to Miss Eleanor T. Cook of Blackstone, Va., December 21.

Lewis Paddock Addoms to Miss Martha Wentworth Suffren, both of Flatbush, Brooklyn, December 26.

Jacob White to Dr. Frances Florence Cohen, both of New York City, December 24.

Deaths

George W. McCafferty, Jr. ⊕ St. Michael, Pa.; University of Pennsylvania, Philadelphia, 1893; aged 48; appointed second assistant physician at the Norristown State Hospital in 1894, first assistant physician in 1897 and chief physician to 1910; in 1909 he was made assistant physician in Kirkbrides, the Pennsylvania Hospital for the Insane, Philadelphia, and in charge of the department of women, where he remained until 1912, when he was appointed assistant physician for the State Hospital for the Criminal Insane, Far View, Wayne County, leaving this position to take up the duties of superintendent of the Somerset Hospital for the Insane, Somerset, in 1916; formerly secretary, treasurer, and reporter of the Wayne County Medical Society; died, December 13, at the Windber Hospital, Windber, Pa., after an operation for appendicitis.

Donald Herbert Currie ⊕ Surgeon, U. S. P. H. S., Boston; Washington University, St. Louis, 1897; aged 42; a member of the Association of Military Surgeons of the United States; who entered the service as assistant surgeon in 1899 was made passed assistant surgeon in 1904, and surgeon in 1912; from 1909 to 1917 on duty in the Hawaiian Islands, where his research work regarding leprosy in the government leper station on the island of Molokai, attracted the attention of medical men throughout the world; representative of the United States at the International Leprosy Congress in Bergen, Norway, in 1909; since 1917 port physician at Boston; died at his home in Brookline, Mass., December 23, from pneumonia following influenza.

George H. Hockett ⊕ Capt., M. C., U. S. Army, Anderson, Ind.; College of Medicine and Surgery (Physiomedico), Chicago, 1910; aged 35; who entered the First Medical Officers' Training Camp at Fort Benjamin Harrison, Ind., and then served at Fort Oglethorpe, Ga., and went overseas in May, 1918, and was placed in charge of the Three Hundred and Thirty-Fourth Sanitary Train, Fourth Division, and participated in the fighting at Chateau Thierry, Soissons, Cambrai, and Argonne Forest, and was proceeding toward Germany with the American Army of Occupation; died, December 1, from heart disease.

Edward Linthicum, Evansville, Ind.; Long Island College Hospital, Brooklyn, 1865; aged 74; at one time a member of the Indiana State Medical Association; formerly professor of clinical surgery in Evansville Medical Colleges; surgeon to the Evansville City Hospital; visiting surgeon and once president of the medical staff of the Deaconess Home and Hospital, and consulting surgeon to St. Mary's Hospital; who served as a medical officer in the war between Serbia and Bulgaria in 1885-1886; died in the Deaconess Hospital, Evansville, December 27, from cerebral hemorrhage.

William Emmet Purviance ⊕ Lieut.-Col., M. C., U. S. Army (retired), Los Angeles; Jefferson Medical College, 1889; aged 53; a member of the Association of Military Surgeons of the United States; who entered the Medical Corps of the Army in 1892, and was retired on account of disability in line of duty, Aug. 6, 1912, was returned to the active list at his own request in 1917, and placed on recruit- ing duty in Los Angeles; is reported to have committed suicide at his home in Los Angeles.

Henry Skillmore Atkins, St. Louis; Beaumont Hospital Medical College, St. Louis, 1887; aged 51; a member of the Missouri State Medical Association; formerly first assistant physician at the Kentucky Insane Asylum, chief assistant at St. John's Hospital, St. Louis, and for eight years superin- tendent of the St. Louis Asylum for the Insane; founder of the Glenwood Sanitarium, Glendale, Mo.; died in St. Luke's Hospital, St. Louis, December 25.

James M. Scott, St. Louis; Washington University, St. Louis, 1853; aged 89; a member of the Missouri State Med- ical Association, and for eight years president of the St. Louis Medical Society; formerly a member of the faculty of his alma mater; and also a professor in the St. Louis Col- lege of Physicians and Surgeons; for two terms a member of the city board of health; died at his home, December 22, from pneumonia.

John Van Doren Bedinger ⊕ Capt., M. C., U. S. Army, Anchorage, Ky.; Johns Hopkins University, Baltimore, 1911; aged 32; associate professor of pediatrics in the University of Louisville from 1913 to 1917; who entered the Army in June, 1917, and served at Fort Oglethorpe, Ga., and Camp Shelby, Hattiesburg, Miss., before going abroad; died in Liverpool, England, October 20, from pneumonia.

Samuel F. Brothers ⊕ Brooklyn; College of Physicians and Surgeons in the City of New York, 1890; aged 54; editor of the *Medico-Pharmaceutical Journal* from 1898 to 1905; also a graduate in pharmacy; founder of *American Medicine;* gynecologist to Zion Hospital and Dispensary, Metropolitan Hospital and Dispensary and Beth Israel Dispensary; died at his home, December 18, from anemia.

Reuben A. Adams, Rochester, N. Y.; Homeopathic Medical College of Pennsylvania, Philadelphia, 1868; aged 77; a veteran of the Civil War; president of the American Institute of Homeopathy in 1916; twice medical director of the Department of New York G. A. R., and in 1915 elected surgeon-general of the G. A. R.; city physician of Rochester in 1874; died at his home, December 9.

Alvin Myers Strusse, Guatemala City, Guatemala, Central America; Jefferson Medical College, 1914; aged 28; who had been doing research work in Guatemala for the Rockefeller Institute, and was president of the local institution in Guatemala City and chief of the supreme council of salubrity; died in the Quirigua Hospital, December 18, from pneumonia following influenza.

William Adam Lieser ⊕ Lieut., M. C., U. S. Army, Celina, Ohio; formerly of Fort Recovery, Ohio; Eclectic Medical Institute, Cincinnati, 1914; aged 34; a specialist on diseases of the eye, ear, nose and throat; who was among the first to enter the service after war was declared; is reported to have died, recently, in France, from wounds received in action.

Benjamin Isaac Coman Buckland, Fleming, N. Y.; University of Michigan, Ann Arbor, 1884; aged 61; a member of the Medical Society of the State of New York, and twice president of the Cayuga County Medical Society; formerly health officer of Cayuga County; died at the home of his brother-in-law in Fleming, December 24.

Carl C. Elmer Boyer, Chicago; Loyola University, Chicago, 1916; aged 32; a member of the staff of the Columbus Hospital; physical director for the north and south parks in Chicago for six years, and in Oil City, Pa., for two years; died at the Columbus Hospital, December 5, from pneumonia following influenza.

Emile L. DeLanney ⊕ Major, M. C., U. S. Army, Omaha; John A. Creighton Medical College, Omaha, 1901; aged 46; assistant professor of the practice of medicine in his alma mater; chief of the medical service at Fort Des Moines, Iowa; died in the post hospital, Fort Des Moines, December 23, from influenza.

William T. Johnson ⊕ Pawnee City, Okla.; Eclectic Medical Institute, Cincinnati, 1885; aged 58; president of the state department of health; formerly professor of diseases of the chest in Lincoln (Neb.) Medical College; was found dead from heart disease in his automobile near Pawnee City, December 18.

John S. Berry, Fort Worth, Texas; University of Louisville, Ky., 1882; aged 60; formerly of Waxahachie, Texas; at one time a member of the State Medical Association of Texas; who was struck by an automobile near his home, December 19, died a few minutes later in St. Joseph's Infirmary.

Wilford Andrew Fair ⊕ Lieut., M. C., U. S. Army, Pleasant Hill, Mo.; University Medical College of Kansas City, Mo., 1909; aged 35; was killed in France, October 6, during the fight in the Argonne Forest, while attempting to aid a brother officer, who had been wounded and was exposed to machine gun fire.

Clarence Alden Macomber ⊕ Lieut., M. C., U. S. Army, New Sharon, Me.; Tufts College Medical School, Boston, 1915; aged 42; on duty at the base hospital, Aviation Field No. 4, Garden City, L. I., was killed in a collision between a run- away team and the ambulance in which he was riding, Decem- ber 20.

Ralph Thomas Saunders ⊕ Lieut., M. C., U. S. Army, Sandusky, Ohio; Ohio State University, Columbus, 1917; aged 25; formerly assistant surgeon at the Ohio State Sol- diers' and Sailors' Home, Sandusky; died in Camp Eustis, Va., October 11, from bronchial pneumonia following influ- enza.

Harrison Briggs Webster ⊕ Major, M. C., U. S. Army, Castine, Me.; Harvard Medical School, 1909; aged 34; who entered the service in 1917, and was on duty with Ambulance Company No. 14, at Fort Benjamin Harrison, Ind., and later went overseas; was killed in action in France, October 12.

Claud Huston Case ⊕ Kansas City, Kan.; University of Kansas, Lawrence and Rosedale, 1907; aged 44; a specialist in diseases of the eye, ear, nose and throat; a member of the staff of Bethany Hospital, Kansas City, Kan.; died in that institution, October 22, from pneumonia following influenza.

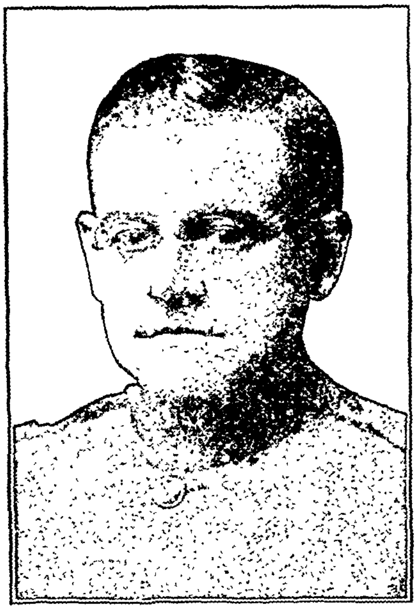
Edward E. Evans, Mercer, Mo.; Missouri Medical College, St. Louis, 1898; aged 50; a member of the Missouri State Medical Association; formerly assistant superintendent of State Hospital No. 1, Fulton; died in Memorial Hospital, Rosedale, Kan., December 12, from pernicious anemia.

Henry Samuel Tanner, San Diego, Calif.; Eclectic Medical Institute, Cincinnati, 1859; aged 87; who first came into notice in the late seventies as an advocate of fasting for the relief of disease conditions of various kinds; died in the San Diego County Hospital, San Diego, December 28.

David D. Bowen, Adams, Mass.; Berkshire Medical College, Pittsfield, Mass., 1861; aged 80; who after his graduation entered the woolen business, and later was in the coal and wood business at Maple Grove; died at the home of his daughter in Adams, December 5, from acute gastritis.

Julian Chew Blakistone, Washington, D. C.; Georgetown University, Washington, D. C., 1906; aged 37; a member of the Medical Society of the District of Columbia; a specialist in urology, and professor of dermatology in his alma mater; died at his home, December 13, from osteosarcoma.

Died in the Service
IN FRANCE
Major Harrison B. Webster, M. C.,
U. S. Army, 1884-1918



Died in the Service
IN FRANCE
Capt. William F. Guilfoyle, M. C.,
U. S. Army, 1882-1918
(See The Journal, Dec. 21, p. 2092)

Died in the Service
IN FRANCE
Lieut. Davis King Summers, M. C.,
U. S. Army, 1888-1019
(See The Journal, last week, p. 59)

Horace Robert Burns ⊕ Denver; Gross Medical College, Denver, 1896; aged 49; a member of the American Academy of Ophthalmology and Oto-Laryngology; a specialist on diseases of the eye, ear, nose and throat; died at his home, October 18, from pneumonia following influenza.

George Buol ⊕ **Lieut., M. C., U. S. Army**, Ravenna, Neb.; University of Nebraska, Omaha, 1910; aged 32; who had been on duty at Camp Funston, Kan., was instantly killed, December 21, when his automobile was struck by a Burlington train at a grade crossing at Streetwater, Neb.

Benjamin Franklin Grove, Baltimore; University of Maryland, Baltimore, 1877; aged 66; at one time a member of the Medical and Chirurgical Faculty of Maryland; a specialist on diseases of the ear and throat; died at his home, December 26, from the effects of a fall in October.

Joseph R. Bluxome, San Francisco; New York University, New York City, 1857; aged 87; attending physician to the DeMilt Dispensary, New York City, in 1865 and 1866, and visiting physician to St. Luke's Hospital, San Francisco, in 1871; died at his home, December 27.

William F. Thomason, Waco, Texas; Medical College of Georgia, Augusta, 1859; aged 79; a Confederate veteran, who served as assistant surgeon in Herrie's Hospital, Atlanta, Ga., during the Civil War, and was afterward a druggist; died at his home, December 21.

William Cleveland Reese ⊕ **Lieut., M. C., U. S. Army**, Wilkes-Barre, Pa.; University of Pennsylvania, Philadelphia, 1910; aged 34; a member of the staff of the Wilkes-Barre City Hospital; died in New York City, October 20, from pneumonia following influenza.

Paul Lee Cocke ⊕ **Capt., M. C., U. S. Army**, Birmingham, Ala.; University of Virginia, Charlottesville, 1899; aged 43; on duty with the American Expeditionary Forces in France; died in Paris, July 27, from concussion of the brain following an automobile accident.

A. Eugene Heimbach, Renovo, Pa.; Hahnemann Medical College, Philadelphia, 1890; aged 55; who underwent operation in the Womans' Homeopathic Hospital, Philadelphia, December 6; died in that institution, December 16, from carcinoma of the stomach.

Harry Everett Gribbin ⊕ Rockland, Me.; Bowdoin Medical College, Brunswick and Portland, Me., 1900; aged 43; a Fellow of the American Academy of Medicine, and a specialist in diseases of the eye, ear, nose and throat; died, recently, from pneumonia.

Max Meyer, New York City; Eclectic Medical College of the City of New York, 1897; aged 64; a practitioner since 1876; professor of chemistry and toxicology and lecturer on histology and pathology in his alma mater; died at his home, December 23.

William Townsend Van Vredenburgh, New Brighton, Staten Island, N. Y.; College of Physicians and Surgeons in the City of New York, 1881; aged 62; died in the Home for Incurables, New York City, December 22, from cerebral hemorrhage.

John P. Hussey, Providence, R. I.; Georgetown University, Washington, D. C., 1903; at one time a member of the Rhode Island Medical Society; died at his home, about December 18.

Edward Embree ⊕ Winterset, Iowa; State University of Iowa, Iowa City, 1889; aged 54; died at his home, November 13, from chronic interstitial nephritis.

William T. Rolston, Cape Girardeau, Mo.; Hahnemann Medical College, 1876; aged 64; died at his home, December 13, from chronic interstitial nephritis.

Herve Gagne, Montreal, Que.; Laval University, Montreal, 1918; aged 30; died in October from pneumonia following influenza.

Thomas Levington Bayne Vaught, Campeche, Mexico; a nongraduate practitioner; aged 36; died, October 2, from pellagra.

Eugene L. Reed ⊕ Atlantic City, N. J.; Jefferson Medical College, 1884; aged 59; died in a sanatorium, December 16.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE QUALITY OF THE MARKET SUPPLY OF PROCAINE

Report of the Council on Pharmacy and Chemistry

The following report has been authorized for publication by the Council. W. A. Puckner, Secretary.

In accordance with its announcement (The Journal, Sept. 22, 1917, p. 1018) to report from time to time on the quality of American-made synthetic drugs, an examination of the market supply of procaine has been made. As explained at the time, the control of synthetic drugs, which, as a result of the war, are now made in this country, is in the furtherance of American industry, for the protection of the public, and in the interest of physicians. Since the manufacture of this class of drugs is to some extent experimental in this country, it is due physicians and the public that they be given the protection which will come from an investigation of the market supply. In view of the occasional reports of accidents with local anesthetics, an examination of the market supply of procaine was deemed particularly desirable. Hence, the A. M. A. Chemical Laboratory was asked to report if the product now offered for sale was satisfactory from a chemical standpoint while the aid of the Pharmacologic Laboratory of Cornell University Medical School was invoked to determine if any of the product was unduly toxic.

Procaine, which chemically is the mono-hydrochloride of Para-amino-benzoyldiethyl-amino-ethanol, is the nonproprietary name selected by the Federal Trade Commission as the official designation for the drug previously known under the proprietary name "novocaine." Before the war procaine was obtainable in this country only through the Farbwerke Hoechst Co., the American representative of the German establishment, Farbwerke, vorm, Meister, Lucius and Bruening, under the name "novocaine." This monopoly on "novocaine" was exercised by virtue of United States patent No. 812,554, which was issued to Alfred Einhorn, Munich, Germany, assignor to Farbwerke, vorm, Meister, Lucius and Bruening, Hoechst a. M., in 1906. With the outbreak of hostilities, Congress passed the Trading with the Enemy Act, and under this, the Federal Trade Commission took charge of the novocaine patent with a view of securing the production of this product in the United States. To ensure an adequate supply of the drug, the Federal Trade Commission on recommendation of the Committee on Synthetic Drugs of the National Research Council, in addition to issuing a license to the Farbwerke Hoechst Company (which license was later transferred to the H. A. Metz Laboratories) granted authority to the Abbott Laboratories and the Rector Chemical Company to manufacture it under the U. S. patent after specimens submitted by these firms had been found satisfactory in the Association's Laboratory and at the Cornell Pharmacologic Laboratory.

After the three licenses had been issued, the Council examined specimens which each of these firms submitted as representing the market supply. These were found satisfactory and the preparations being marketed in conformity with its rules, the Council admitted procaine-Abbott, procaine-Farbwerke (novocaine), and procaine-Rector to New and Nonofficial Remedies as brands of procaine.

To obtain specimens representing the market supply, orders for the three brands of procaine were recently placed with pharmaceutical firms in New York, Baltimore and San Francisco. The Baltimore and San Francisco firms supplied specimens of procaine-novocaine brand and procaine-Rector brand but reported that the Abbott brand was not procurable. The New York correspondent was able to supply procaine-Rector only. As the entire output of the Abbott Laboratories was stated to go to the Government, specimens of this product were obtained through the Surgeon-General of the Army from the General Purchasing Office, Medical Dept., U. S. Army. The following specimens were obtained and examined:

1. *Procaine-Abbott, 6 specimens:* The first specimen bore no serial number but the five later specimens were designated respectively, No. 89999, No. 89998, No. 89997, No. 89996, and No. 810995 representing batches from which shipments are to be made on contracts placed by the General Purchasing Office, Medical Department, U. S. Army, with the Abbott Laboratories of Chicago.

2. *Procaine-novocaine brand, 4 specimens:* These were designated respectively, A56, A57, A63, and A67. The first two specimens were labeled "Manufactured by the Farbwerke-Hoechst Co. at the H. A. Metz Laboratories." The third specimen (not in original container) was labeled "H. A. Metz Laboratories" and the fourth was marked "Manufactured by the H. A. Metz Laboratories."

3. *Procaine-Rector, 3 specimens:* Each bore the statement "Manufactured by the Rector Chemical Company" but had no "lot number."

Report of the A. M. A. Chemical Laboratory

To determine the quality of procaine now offered to the medical profession, the several specimens of each brand which had been purchased were submitted to the tests employed when specimens were previously examined for the Subcommittee on Synthetic Drugs of the National Research Council, and for the Council on Pharmacy and Chemistry. These tests were essentially those of New and Nonofficial Remedies and of the German Pharmacopoeia; it is, of course, not in the U. S. Pharmacopoeia. They require that the specimens shall respond to tests of identity for procaine (para-amino-benzoyldiethyl-amino-ethanol-hydrochloride); shall be odorless and colorless crystals or crystalline powder; shall melt at 153 to 155 C.;[1] shall be free from metallic impurities, and readily carbonizable matter, and on incineration leave not more than 0.1 per cent. ash.

In the accompanying table the results of the examination are given. For comparison the findings for the specimens examined previously are included.

From this examination it appears that all the specimens of procaine received complied satisfactorily with all tests of identity and purity with the following exceptions: (1) One specimen of procaine-Abbott had a melting point slightly below the permitted range; however, the last five specimens had the required melting point. (2) Five specimens of procaine-Abbott and the last three specimens of procaine-Rector were not entirely colorless, but had a yellow or light brown tinge.

Report from the Cornell Pharmacologic Laboratory

The following is the report of the toxicity determinations carried out on the specimens of procaine above enumerated, in the Pharmacologic Laboratory of Cornell University, Medical School, by Dr. R. A. Hatcher with the assistance of Dr. C. Eggleston.

Because of the serious or even fatal accidents occasionally reported from the use of local anesthetics (The Journal, Jan. 26, 1918, p. 258), it was thought prudent to determine that specimens of procaine should not be unduly toxic under normal conditions. Such tests have been made for the Subcommittee on Synthetic Drugs when the issuance of licenses for the manufacture was under consideration and have been a prerequisite to the acceptance for New and Nonofficial Remedies.

Twenty-five milligrams of drug per kilogram weight of cat in 5 per cent. solution is injected intravenously, and after 15 minutes, the same amount is again given in the same way. The dose administered in the test corresponds to over 1.5 gm. of drug for an adult of average weight administered intravenously, by which route the toxicity of the drug is far greater (approximately ten times as great) than by the subcutaneous method ordinarily used in clinical practice.

---

[1] U. S. patent number 812,554—the novocain patent—declares that the salt melts at 156 C. Evidently based on this, both the German Pharmacopoeia and New and Nonofficial Remedies give this melting point. Two specimens of German made novocain obtained from our files, stated to be manufactured by Farbwerke-Hoechst vorm. Meister, Lucius, and Bruening, Hoechst a.M. were found to melt respectively between 154 and 155 C. and between 153.5 and 154.5 C. when the melting point was determined according to the directions of the U. S. Pharmacopoeia, 9th revision. The various specimens examined at that time melted between 153 and 155 C. and it was decided to permit this range.

When the several market specimens of procaine were tested in this way, the animals so tested succumbed in no case. These results indicate that none of the specimens is to be considered dangerous when used in ordinary dosage for normal individuals. (Since the accidents attending the use of procaine depend on abnormal conditions not understood at present, no responsibility for the safety of the drug can be assumed as a result of these experiments.)

Several specimens of procaine-Rector and five of procaine-Abbott are decidedly brownish in color even when finely powdered and yield yellowish solutions.[1] All the earlier specimens from the Abbott Laboratories and from the Rector Chemical Company were beautifully white and crystalline.

Brand	Date Received	Color	Melting Point	Ash
Procain (Abbott), from Committee on Synthetic Drugs....	12/21/17	White	154-155 C.	None
Procain (Abbott), submitted to Council P. and C.	1/29/18	White	153.5-154.5 C.	None
Procain (Abbott), Gen. Pur. Off. U. S. Army................	8/31/18	White	152.5-153.5 C.	None
Procain (Abbott), Gen. Pur. Off. U. S. Army, No. 89999.....	9/30/18	Slight brownish tint	153-154.5 C.	None
Procain (Abbott), Gen. Pur. Off. U. S. Army, No. 89998.....	9/30/18	Slight brownish tint	153-154.5 C.	0.005%
Procain (Abbott), Gen. Pur. Off. U. S. Army, No. 89997.....	10/ 8/18	Slight brownish tint	153-154 C.	None
Procain (Abbott), Gen. Pur. Off. U. S. Army, No. 89996.....	11/ 4/18	Slight brownish tint	153.5-154.5 C.	None
Procain (Abbott), Gen. Pur. Off. U. S. Army, No. 810995....	11/ 4/18	Slight brownish tint	153.5-154.5 C.	None
Procain (Farbwerke Hoechst Co.), submitted to Council....	10/24/17	White	153-154 C.	None
Procain (Farbwerke Hoechst Co.), submitted to Council....	12/10/17	White	153-154.5 C.	None
Procain (Farbwerke Hoechst Co.), submitted to Council, market spec. "A56"............	8/ 9/18	White	153.5-154.5 C.	None
Procain (Farbwerke Hoechst Co.), submitted to Council, market spec. "A57"............	9/ 9/18	White	153.5-154.5 C.	None
Procain (H. A. Metz Lab.), market spec. "A63"............	8/23/18	White	153-154 C.	None
Procain (H. A. Metz Lab.), market spec. "A67"............	9/23/18	White	153-154 C.	0.018%
Procain (Rector), from Com. on Synthetic Drugs............	12/18/17	White	153-154.5 C.	None
Procain (Rector), market spec.	8/20/18	Slight brownish tint	153-155 C.	None
Procain (Rector), market spec.	8/23/18	Slight brownish tint	153-155 C.	None
Procain (Rector), market spec.	8/23/18	Slight brownish tint	153-154.5 C.	None

The following tests were also made: About 0.01 to 0.02 gm. procaine was added to about 10 to 15 c.c. distilled water contained in a test tube, and this placed in a bath of boiling water for one hour. The solutions were then cooled and examined. After standing over night, they were examined again. No deposit of any sort and no change of color could be detected in any case.

When the matter of the discolored specimens of procaine was referred to the Rector Chemical Company for explanation, the firm wrote that some months ago for a short time for some unexplainable reason its procaine was slightly yellowish in color, but that every batch was carefully tested and found to answer all chemical requirements. The firm stated that the product which it has sent out for some time past has been white and yields a colorless solution.

To a like inquiry the Abbott Laboratories replied that the five samples which were found discolored were products manufactured by the Rector Chemical Company and represented goods which it had purchased to assist in filling delayed orders, because the firm had found itself unable to keep pace with the demand on account of delay in securing needed apparatus. The firm submitted protocols to show that the procaine made by it, by Rector and by Metz were of equal toxicity.

So far as the evidence goes, there is nothing to indicate that the yellowish or brownish colored specimens of procaine are seriously impure. On the contrary, the compliance with the chemical and toxicologic tests indicates that the color is due to an insignificant trace of some colored substance produced in the manufacturing process. In view of this, the Council considers the use of the discolored product to be justified in the present emergency, although it would urge that for the future the supply of procaine should be free from color and also comply to the tests of purity. It makes this request in the interest of the medical and dental professions, which use the drug, and also in a desire that in the manufacture of synthetic drugs, the United States shall occupy a high place.

Correspondence

"THE ROENTGENOLOGIC STUDY OF EMPYEMA CAVITIES"

To the Editor:—In his article on "The Roentgenologic Study of Empyema Cavities" (The Journal, December 14, p. 1975), Dr. Franklin A. Stevens advocates an oil emulsion of bismuth subnitrate for the outlining of empyema cavities, as a substitute for bismuth paste. His reason for employing the oil mixture in preference to the petrolatum as given is that the oil mixture will fill all the crevices of the cavity and prevent bismuth absorption. Wishing to verify his experience, I desired to determine whether the oil and bismuth and powdered acacia will make a stable homogeneous mixture. I therefore made up the mixture as described and left it in the test tube overnight. In the morning I found all the bismuth at the bottom of the test tube and the pure transparent oil on top. Again the test tube filled with a 10 per cent. bismuth paste shows it to remain homogeneous.

This, in my opinion, makes the mixture of oil and bismuth not only unsuitable for the purpose but also dangerous, because the pure bismuth might separate and gravitate into the deepest recess between the dome of the diaphragm and the pleura and make it difficult to remove and in time cause absorption, with its toxic effects. If the oil and bismuth mixture were injected into tortuous sinuses, at the end of which were abscess cavities, the bismuth would remain in the abscess cavities, while the oil would run out and cause very serious complications.

Bismuth poisoning is not eliminated by substituting oil for petrolatum; but we have demonstrated that the accidental occurrence of bismuth poisoning can be prevented by proper technic in employing the bismuth paste.

In order that the proper preparation of the bismuth paste may be better known, as it is used at the present time, I give herewith the formula for its preparation:

The materials required are:
1. Bismuth subnitrate, chemically pure.
2. Yellow petrolatum (best grade).
3. White wax.
4. A large porcelain mixing bowl.
5. A spoon.
6. A large enamel jar, with a cover, for storing the paste.
7. Several small enamel jars with covers for liquefying paste at the time of use.
8. Adhesive straps for the covers of the jars, to keep moisture and dirt from contaminating the paste.
9. Water bath for heating the paste.
10. Sterile rubber gloves, towels, etc., for aseptic technic.

Bismuth paste is a 10 per cent. mixture, one part of bismuth subnitrate to nine parts of petrolatum, with a small amount of white wax (2 ounces to 10 pounds of paste). The mixing bowls, jars and spoon are sterilized. The petrolatum is sterilized for twenty minutes in the original container in the autoclave. The bismuth subnitrate is sterile when it comes from the manufacturer and so does not have to be resterilized. The mixing bowls and jars must be absolutely dry, as the slightest amount of water produces a curdling of the paste and it is then useless.

---

[1] A specimen of procaine recently sent the Council by the Metz Laboratories had a faint tinge of yellow, but, like the discolored Rector and Abbott specimens, complied with the identity and purity tests for procaine.

The bismuth subnitrate is poured into the mixing bowl and all lumps smoothed out with the spoon. A sufficient amount of petrolatum, which is still in a liquefied condition from the sterilizing, is slowly poured into the bismuth, to make a stiff paste. This mixture is then stirred for an hour until it is a smooth, bright, yellow, homogeneous paste. This is the most important step in the process, and if it is not carried out carefully, the paste will not be homogeneous.

To the balance of the nine parts of the liquefied petrolatum a small amount of white wax, which has been heated to liquefaction, is added (2 ounces to 10 pounds), and then this mixture is gradually added to the thick paste, being stirred constantly. The resulting product should be a light yellow, smooth, homogeneous paste, which, on cooling, becomes congealed without the precipitation of the bismuth.

From time to time, small amounts of this paste (from 8 to 10 ounces) are transferred to small jars in which the paste is liquefied and from which it is used. These jars should not be more than half full, and great care should be taken not to get any water into the paste while heating it.

The syringes that are used are both glass and metal, the barrel holding from one-half ounce to 2 ounces of paste. These syringes have different shaped points and nozzles, according to the demands of the case. The syringes are sterilized and kept in sterile towels until they are to be used, when they are filled with the liquefied paste.

Emil G. Beck, M.D., Chicago.

"FOCAL INFECTIONS OF THE EYE FROM THE INTESTINAL TRACT"

To the Editor:—Apropos of Dr. J. G. Dwyer's article in The Journal, December 21, on "Focal Infections of the Eye from the Intestinal Tract," I recently had a case that illustrates the influence of gastro-intestinal toxemia in certain eye conditions:

A girl, aged 18 years, consulted me in the middle of April, 1918, because of typical serous iritis of the right eye for which she had been under treatment two weeks at a local clinic. There were by this time slight iritic synechiae and some corneal infiltration. Examination of the heart and lungs elicited nothing abnormal. The teeth were in good condition. The patient had slightly buried tonsils; there was no exudate either on the surface or in the crypts, nor was there a history of frequent attacks of tonsillitis. The nose as well as the neighboring sinus cavities were evidently normal, at least clinically so. There was no history of rheumatism or any joint affection. Menstruation was normal. In fact, outside of slight paleness due to the patient's rather sedentary occupation, that of a stenographer and bookkeeper, the girl had evidently enjoyed good health until the present attack. She was put at once on the routine antiiritic treatment (calomel for the bowels, atropin in oil locally, acetylsalicylic acid internally, dark coquilles, hot applications, bland diet, etc.) and told to report to a local hospital for a Wassermann test, which was negative. A von Pirquet test yielded the same result. Under this treatment the eye seemed to be getting along quite well, as the patient, luckily, was in a position to give up her work and followed religiously the instructions given her, when she reported, May 27, with the unmistakable signs of a beginning iritis in the other eye. On inquiry she admitted that on the previous day she had had a heavy meal of meat and tomatoes, and later in the day had partaken rather freely of strawberries. A goodly dose of calomel with sodium bicarbonate seemed to put her on the right track again, and though the attack of iritis in this eye could not be prevented, the condition was under our complete control until a month later, when another gastro-intestinal indiscretion caused a slight exacerbation in both eyes, and retarded the treatment to some extent. A little later there developed a mild degree of optic neuritis, with blurring of the outlines of the disk and slight swelling of the nerve head, without, however, in any way affecting the vision or the fields; by this time the deposits on the posterior surface of the cornea were almost completely absorbed. The recovery now continued uninterruptedly, and by the middle of August the patient was able to return to her work. A month later the outlines of the disk began to emerge, and the disk gradually took on its natural form and color. Potassium iodid was given during the last two months of treatment. I might observe that while under my care the patient had two marked attacks of urticaria.

The question in my mind is: Can a case of this kind really be called a focal infection, in the common acceptation of the term, or does it more properly belong to that class of disturbances, with the iris as the locus minoris resistentiae, caused by protein sensitization of ingested food? In either case the question opens up a wide vista of scientific investigation, on the results of which depends the solution of many puzzling pathologic phenomena.

Alexander Rovinsky, M.D., New York.

TREATMENT OF INSOMNIA

To the Editor:—I have read with interest Dr. Mautz' letter on insomnia in The Journal of December 14. In my own case (I am of a nervous temperament) business affairs have often produced a sleepless night. I have tried counting, deep breathing, etc., (and have avoided drugs) without success. I have also tried getting up and walking around for a while, only to resume my busy thoughts on returning to the pillow. Suddenly an inspiration: Get out of bed; become interested in some humerous story, such as one of Mark Twain's; get to laughing; go to bed with a good giggle on: Morpheus takes a grip on the throat of business, and there you are—asleep.

S. C. Priest, M.D., Newark, Ohio.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

COMMISSIONS IN THE RESERVE CORPS, INACTIVE

To the Editor:—A number of physicians who volunteered their services during the war received notices that they had been recommended for commissions, and that commissions and orders would be issued through the Adjutant-General's Office. In many cases the commissions and orders were not received and, of course, will not be received since the armistice has been signed. Most of these physicians had fully prepared themselves to report for duty at a greater or lesser sacrifice. They no doubt will be very grateful to have the government recognize their willingness to assist in the emergency. Would it be reasonable to expect the government to issue the delayed commissions, and immediately on acceptance, to muster out the recipients? This mark of appreciation would entail very little extra work, and no expense.

W. L. R.

Answer.—We are informed that the War Department will probably issue commissions in the Reserve Corps, inactive, to those medical men whose applications for appointment had received the final approval of the Surgeon-General on or before Nov. 11, 1918. There may, of course, be some delay in the issuing of these appointments. If nothing is heard from the War Department within five or six weeks, the physician might well write directly to the Adjutant-General's Office, detailing the circumstances and requesting the issuing of the commission.

LITHIUM CARBONATE—PHENOL CRYSTALS

To the Editor:—1. Is not lithine carbonate, as mentioned in Current Medical Literature, Nov. 9, 1913, p. 1620, Abstract 109, lithium carbonate? 2. What is glacial phenol described in Abstract 45, p. 1616?

F. M. P.

Answer.—1. The Spanish term used is "carbonato de litina" and in the French summary given with the article the chemical is designated "carbonate de lithine." Both of these terms are the equivalent of lithium carbonate, which should have been the English word used.

2. The French term "acide phénique neigeux" should have been translated "phenol crystals."

Book Notices

TRENCH FEVER. Report of Commission of the Medical Research Committee, American Red Cross. Members of Commission: Richard P. Strong, Major, M. R. C.; Homer F. Swift, Major, M. R. C.; Eugene L. Opie, Major, M. R. C.; Ward J. MacNeal, Captain, M. R. C.; Walter Baetjer, Captain, M. R. C.; A. M. Pappenheimer, Captain, M. R C.; A. D. Peacock, Captain, R. A. M. C. (T) and David Rapport, First Lieutenant, M. C. Prepared for publication by Richard P. Strong. Cloth. Pp. 446, with illustrations. New York: Oxford University Press, 1918.

This commission consists of the following members of the Medical Corps. Majors Richard P. Strong, Homer F. Swift and Eugene L. Opie; Captains Ward J. MacNeal, Walter Baetjer, A. M. Pappenheimer and A. D. Peacock, and Lieut. David Rapport. A report of the investigations and conclusions has just been issued in a large volume. This will be of value to others pursuing investigations on the subject.

In carrying out the investigations, since the disease is not transmissible to animals, it was necessary to secure the assistance of volunteers, and eighty-two American soldiers, after having the conditions of the experiment fully explained to them, volunteered their services. The work was carried out at a stationary hospital of the British Expeditionary Forces, the laboratory apparatus and supplies with funds being furnished through the American Red Cross. The researches are extensive, including examination and inoculation of the volunteers and the study of numerous soldiers subject to the disease. The most important facts demonstrated by the investigations are that:

1. Trench fever is a specific, infectious disease; it is not a modified form of typhoid or paratyphoid fever, and is not related, from an etiologic standpoint, to these diseases.
2. The organism causing the disease is a resistant filtrable virus.
3. The virus causing trench fever is present particularly in the plasma of the blood of trench fever patients, and such plasma will produce the disease on inoculation into healthy individuals.
4. The disease is transmitted naturally by the louse *Pediculus humanus* Linn., var. *corporis,* and this is the important and common means of transmission. The louse may transmit the disease by its bite alone, the usual manner of infection, or the disease may be produced artificially by scarifying the skin and rubbing in a small amount of the infected louse excrement.
5. A man may be entirely free from lice at the time he develops trench fever, the louse that infected him having left him some time previously as its host, and the louse need only remain on the individual for a short period of time in order to infect him.
6. The virus of trench fever is also sometimes present in the urine of trench fever patients and occasionally in the sputum, and the disease may be produced in man by the introduction of the virus in the urine or sputum through the scarified or otherwise abraded skin.
7. Since the urine and sometimes the sputum of trench fever patients are infective, these should be sterilized in order to avoid the possibility of accidental infection from them.
8. In order to prevent trench fever or limit its spread, and thus save man power for the armies, greater efforts must be made to keep soldiers in general from infestation with lice.

Usually the complete study of any infectious disease, from its first description as a clinical entity to the discovery of its etiology, pathology and control, requires many years, sometimes many generations. Here in a single controlled research a disease has been thoroughly studied and the method of control discovered during three or four years.

The Enterprising Pharmaceutical House and Its "Remedies."—Let an enterprising pharmaceutical house bring forward a remedy for a certain disease and advertise it in a pseudoscientific way, and the profession will not fail to adopt and use it until another advertised remedy displaces it. It does not matter whether it be a revived old remedy, a new one, or an old one dressed in a new garb; whether it be a chemical or an animal extract, a heterogeneous vaccine, the profession is always ready to welcome the new medicinal recruit and give it a place in its multitudinous armamentarium. Wherein lies the fault? It is due, partly, to our blind devotion to our old-time drugs, which should have been relegated to the attic years ago, and, partly, to our fickleness created by overenterprising pharmaceutical houses. —Ravitch and Steinberg, *Kentucky Medical Journal.*

COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 14. Chairman, Dr. S. W. Welch, Montgomery.

DISTRICT OF COLUMBIA: Washington, Jan. 14-16. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

KANSAS: Topeka, Feb. 11. Sec., Dr. H. A. Dykes, Lebanon.

MISSOURI: St. Louis, Jan. 28-30. Sec., Dr. G. H. Jones, State House, Jefferson City.

NEW MEXICO: Sante Fe, Jan. 13. Sec., Dr. W. E. Kaser, East Las Vegas.

NEW YORK: Jan. 28-31. Albany, Buffalo, New York City and Syracuse. Mr. Herbert J. Hamilton, Asst. Prof. Exams., New York Dept. of Education, Albany.

SOUTH DAKOTA: Pierre, Jan. 14. Sec., Dr. P. B. Jenkins, Waubay.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

WISCONSIN: Madison, Jan. 14. Sec., Dr. J. M. Dodd, 220 E. 2d St., Ashland.

WYOMING: Moorcroft, Feb. 12-14. Sec., Dr. H. E. McCallum, Laramie.

Medical Schools and Medical Students in India

A recent number of the *Indian Medical Gazette* contains a list of five medical "colleges" having 2,491 students enrolled and fourteen medical "schools" with 2,869 students. There are, therefore, nineteen medical teaching institutions having altogether 5,360 students, an average of 282 students each. The figures in detail are as follows:

MEDICAL COLLEGES	Men	Women	Total
Grant Medical College, Bombay	653	52	705
Madras Medical College	416	32	448
Lahore Medical College	225	7	232
Calcutta Medical College	946	19	965
King George's Medical College, Lucknow	136	5	141
Totals	2,376	115	2,491
MEDICAL SCHOOLS			
Campbell School, Calcutta	372	18	390
Dacca School	278	2	280
Royapuram School, Madras	269	11	280
Prince of Wales School, Tanjore	132	..	132
Vizagapatam School	112	..	112
Hyderabad School	137	..	137
Poona School	168	..	168
Ahmedabad School	198	2	200
Agra School	557	61	618
Ludhiana School (Women)	...	21	21
Burma School	93	7	100
Temple School, Patna	131	..	131*
Cuttack School	146	5	151
Berry White School, Assam	149	..	149
Totals	2,742	127	2,869
Totals both Colleges and Schools	5,118	242	5,360

* Includes 96 compounders.

Reports in the files of the Council on Medical Education show that the "colleges" named in the first list are of a standard recognized by the Conjoint Board of London, but the "schools" are not so accredited.

The article states that the accommodations for students in the medical teaching institutions are very inadequate, and that the question of increasing these accommodations is receiving serious attention by all local governments. It is common knowledge that one of the greatest needs in India—as in China—is of physicians having a knowledge of and who practice scientific medicine.

Massachusetts July Examination

Dr. W. P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at Boston, July 9-11, 1918. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 56 candidates examined, 40, including 1 nongraduate and 13 osteopaths, passed, and 16, including 10 osteopaths, failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Yale University	(1918)	82.9
College of Physicians and Surgeons, Baltimore	(1902)	75
Johns Hopkins University	(1918)	83.4

Boston University	(1918)	77.6
College of Physicians and Surgeons, Boston	(1917)	75
Harvard University (1918) 80, 80.3, 80.4, 81.2, 83.8, 84.6.		
Middlesex College of Med. and Surgery	(1918)*	76.5, 81.1
Tufts College Med. School (1916) 79.5; (1917) 80.1;	(1918)	75, 75, 75.1, 80.5, 81.2.
University of Michigan Medical School	(1916)	79
University and Bellevue Hospital Med. Coll.	(1917)	80.6
Hahnemann Med. Coll. and Hosp. of Philadelphia	(1911)	82.1
University of West Tennessee	(1916)	75
University of Vermont	(1918)	84
McGill University	(1918)	83.1
FAILED		
College of Phys. and Surg., Boston.... (1915) 68.5;	(1916)	65.5, 66.5
Middlesex College of Medicine and Surgery	(1918)*	60
Tufts College Medical School	(1918)	72.3
University of Berlin	(1903)	58.1

* Graduation not verified.

Dr. Bowers also reports that 5 candidates were licensed at the *special examinations held* for War Service, June 11-12, July 30-31, and Aug. 8, 1918. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Harvard University (1917) 86;	(1918)	79.7, 82.2
Tufts College Medical School	(1918)	78.3
University of Vermont	(1911)	79.2

Idaho October Examination

Dr. Ray H. Fisher, secretary of the Idaho State Board of Medical Examiners, reports the written examination held at Boise, Oct. 1-2, 1918. The examination covered 11 subjects and included 110 questions. An average of 75 per cent. was required to pass. Eleven candidates took the physician's and surgeon's examination, including 2 osteopaths, all of whom passed. *Seven candidates were licensed through reciprocity.* The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
State University of Iowa Coll. of Homeo. Med.	(1889)	76
Louisville Medical College	(1894)	75
University of Michigan Medical School	(1891)	78
University Medical College of K. C.*	(1897)	80
University of Buffalo	(1899)	75
Western Reserve University	(1918)	84
Hahnemann Med. Coll. and Hosp. of Philadelphia	(1917)	77
University of Tennessee	(1894)	75
University of Texas	(1910)	80

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of Colorado	(1916)	Utah
George Washington University	(1916)	Washington
Drake University	(1907)	Washington
Baltimore University	(1903)	New Mexico
Michigan College of Medicine and Surgery	(1904)	Utah
Missouri Medical College	(1882)	Utah

Michigan October Examination

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 8-10, 1918. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Three candidates were examined, all of whom passed. The following colleges were represented:

Dr. Harison also reports that 14 candidates were licensed through reciprocity from Sept. 3 *to and including* Nov. 20, 1918. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Johns Hopkins University	(1918)	87.8
University of Michigan Medical School	(1918)	86.8
University of Michigan Homeo. Med. School	(1918)	86.1

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Bennett College of Eclectic Med. and Surg.	(1898)	Illinois
Hahnemann Med. Coll. and Hosp. of Chicago	(1910)	Illinois

Diagnosing Is Practicing Medicine—Chiropractor

(State v. Rolph (Minn.), 167 N. W. R. 553)

The Supreme Court of Minnesota, in affirming an order denying the defendant, a chiropractor, a new trial after she had been convicted of practicing medicine without a license, in violation of Section 4981 of the General Statutes of Minnesota of 1913, holds that the act of a person who styles himself a doctor, *in* receiving a patient who has applied to him for medical attention, and examining such person and diagnosing his ailment or disease and recommending an operation as treatment therefor, *is practicing medicine within* the meaning of the Minnesota statute prohibiting the practice thereof without a license, though he prescribes no drug and administers no specific treatment to the patient. The court says that the science of diagnosing human diseases and human ailments has come to be a distinct branch or department of the medical profession; the diagnostician *limiting his efforts* to a discovery of the disease or ailment from which the patient may be suffering, its character and location, leaving the treatment thereof to some other physician or surgeon. This is a matter of common knowledge. And it requires no discussion or argument to demonstrate that the physician who thus applies his learning and energies *is performing a highly important duty of the profession,* and is engaged in the practice thereof, though he prescribes no drug and administers no specific treatment. If a physician so limiting his services is practicing medicine, of which there can be no doubt, then in the case at bar the question whether the defendant, in diagnosing the ailment of the person named in the indictment, was likewise engaged was at least a question for the jury.

The evidence disclosed that the defendant was not a licensed physician and surgeon, but was a chiropractor who *for several years* had been practicing at Minneapolis. Some time prior to the date charged *in the indictment* she advertised that she would be at Granite Falls on a given date, to remain for three days to extend relief to those who might apply to her. She held herself out as Dr. B. Elizabeth Rolph, and posters were distributed *announcing* her coming. Cards *with her name as just stated were placed on the doors of* her rooms at the hotel, where she received patients. She was accompanied by a nurse, who assisted in the examination *of persons applying* for help, and in the administration of the treatment given them. They shared equally in the profits. The person named in the indictment, who had been in ill health a long time, was received as a patient, and an examination and diagnosis made by the defendant, assisted by the nurse, disclosed an abdominal tumor, for which the defendant recommended an operation by some competent surgeon. The defendant did not attempt to treat that condition, but did apply to the patient the usual chiropractic treatment, and at the conclusion of all a fee of $2 was charged, and paid. The question was raised whether *the fee* was paid for the preliminary examination or diagnosis or for the treatment; but the dispute was not of serious moment. The examination and treatment constituted one transaction, and whether the fee was exacted for the treatment, excluding the diagnosis, was a fair question of fact. The trial court held it to be immaterial. That the evidence showed that the defendant administered chiropractic treatment to other patients, for the same fee each, was important only as indicating that the examination of the particular patient with the advice of an operation was not an isolated transaction or a neighborly act. The evidence clearly justified the jury in finding the facts substantially as charged in the indictment, and thereon in concluding that the defendant was practicing medicine within the meaning and in violation of the Minnesota statutes.

The indictment was *sufficient,* although the charging part thereof was limited to the specific acts deemed a violation of the statute, and did not charge a commission of the crime *in general terms.*

Damages Allowed Aged Physician for Injuries

(Rust v. Washington Tool & Hardware Co. (Wash.), 172 Pac. R. 846)

The Supreme Court of Washington affirms a judgment for $2,500 damages in favor of the plaintiff, a physician 78 years of age, who was injured by falling into an open elevator shaft in a store where he was making purchases. The court says that an agent of a company that carried a liability policy of insurance on the elevator having been at once summoned after the accident, on payment of $20 obtained from the plaintiff a release and affidavit exonerating the defendant, but there was evidence that the plaintiff did not know what he was doing when he signed them. In deciding against the contention that the award of $2,500 for the injury sustained was excessive, the court says that the evidence showed that the plaintiff, although at the advanced age of 78 years and with but a short expectancy of life, was still practicing his profession as a physician, and was incommoded therein by the condition of his foot, which still caused him pain in its use. At the time of the accident he suffered a dislocation of the kneecap, cuts and bruises about the head and body, and a dislocation of the bones of his foot. He was confined to his bed for several weeks, and compelled for seven or eight months to use crutches. The ankle was stiffened, the bones of the foot had fallen down, there was no arch, and the heel bone was left unaided to sustain his weight. The bones were in such a condition that they must be kept in place by tight bandages of adhesive tape, a heavy iron form must be used in the shoe so as to create an artificial arch, and a cane was necessary to assist in walking. The injury was permanent and one that could not be remedied by an operation. The plaintiff still suffered pain in the use of the foot and whenever the bandages were adjusted. While the award appears to the supreme court large, in view of the advanced age of the plaintiff, the trial court in the exercise of its discretion refused to make a reduction, and the supreme court feels that it would not be warranted, under the circumstances and showing made, in interfering with the award returned by the triers of the fact.

Nature of Action for Death from Abandoning Patient

(Cochran v. Laton (N. H.), 103 Atl. R. 658).

The Supreme Court of New Hampshire, in overruling the defendant's exceptions in this action brought by an administrator and resulting in a verdict for the plaintiff, says that the only question of law raised by the defendant's exceptions to the court's charge, its refusal to charge, and to the admission of evidence as to the deceased's expectation of life was whether an action to recover for a death caused by a physician's abandoning his patient is an action of tort for physical injuries to the person within the meaning of Public Statutes, Chapter 191, Sections 8-13, Section 8 providing in substance that such an action shall survive in the way and to the extent set forth in the following five sections, and the court holds that the action is such a one of tort within the meaning of the statute.

Charitable Institutions Not Within Provisions of Workmen's Compensation Act

(Zoulalian v. New England Sanatorium & Benevolent Association (Mass.), 119 N. E. R. 686)

The Supreme Judicial Court of Massachusetts, in overruling exceptions to a verdict for the defendant, says that this was an action for *personal injuries* received by the plaintiff while in the employ of the defendant and at work on a buzz planer. The defendant was a corporation "for the purpose of founding a hospital or charitable asylum . . . for the care and relief of indigent or other sick or infirm persons . . . and in no manner directly or indirectly for private profit or dividend paying, to any one." It was plain that the objects of the corporation being benevolent and charitable, it must be held to be a valid public charity.

It was the contention of the plaintiff that the defendant was within the provisions of the workmen's compensation act (Statutes of 1911, Chapter 751, and acts in amendment thereof); but the court is unable to agree with this contention. While it is provided by Section 2 of Part 1 that "the provisions of section one shall not apply to actions to recover damages for personal injuries sustained by domestic servants and farm laborers," it does not follow that all other employees who may be injured in the course of their employment are within the terms of the act. Undoubtedly the rules of law declared by this court relating to persons injured while in the employ of charitable institutions may be changed by the legislature, still that such change was made by the workmen's compensation act is not to be inferred in the absence of a plain intention on the part of the legislature to that effect.

It never has been held in this commonwealth that a charitable institution was liable for negligence; on the other hand, it has been expressly held that such institutions are not liable for negligence of their servants or agents. For many years prior to the enactment of the Statute of 1911, Chapter 751, this court in numerous decisions had uniformly held that a charitable institution was not liable for personal injuries due to the negligence of its servants or agents; and it is to be assumed that the legislature had the existing law in mind when the statute was passed. The court is of the opinion that, considering the statute as a whole together with its manifest purpose and the objects sought to be accomplished by it, it was not intended thereby to change the law as it previously stood and include employees of charitable institutions.

2. **Does Surgery Ever Cure a Case of Cancer.**—Unless there be evident metastases and the patient can stand operation, Tate believes that it is the physician's duty to mankind to operate without delay, even if there be only a temporary improvement. A hopeless case, where there is no chance for even the prolongation of life, should never be subjected to surgery.

5. Abstracted in The Journal, Oct. 25, 1918, p. 1434.

6. **Abdominal Pregnancy at Term.**—Noble's patient became pregnant in November. Her condition was diagnosed in May. She was laparotomized in August. Pulling aside the margins

of the incision, a very unusual picture was revealed. A very large area of very thin, almost transparent, amniotic sac lay beneath the abdominal wall, through which could plainly be seen the body of the fetus in vigorous activity. The omentum and transverse colon lay covering across the upper zone of the sac to which they were very intimately adherent. There were adhesions between the amniotic sac and the parietal peritoneum in front. It seemed that nature had everywhere utilized the viscera as a substitute for the uterine wall, but had been scrupulously careful to prevent attachment to the unstable abdominal wall in front. An attempt was made to dissect the omentum and transverse colon from the amniotic sac, but the fusion between these substances was so close that rupture of the sac almost immediately took place. Through this rent, a well-developed baby was delivered, crying lustily. The cord was tied and cut and attention then given to the placenta and its membranes. The membrane was adherent to the omentum, transverse colon, coils of intestines and mesentery. The placenta, which was very large, was attached to the mesentery of the sigmoid, the posterior aspect of the broad ligament and the floor of the pelvis. Everywhere the vessels coming to this area were enormously enlarged, many of the venous channels in the mesentery and the broad ligament being as large as a finger. The fetal head had been resting on that portion of the placenta covering the floor of the pelvis. The child weiged 8 pounds and 6 ounces when delivered.

19. **Ligation of Inferior Vena Cava.**—During the removal of a growth lying in front of the lower lumbar vertebrae and behind the peritoneum, the vena cava was torn diagonally across more than half of its circumference. The edges could not be approximated so as to make a safe suture, so Noble ligated above and below with plain catgut. Trusting to the collateral circulation between the iliacs and epigastrics to take care of the return of the blood from the lower extremities, the cut in the posterior peritoneum was closed with a running catgut suture, and the abdomen closed in the usual way without drainage. This patient, a woman, aged 62 years, made an uninterrupted recovery without swelling or edema of the legs, or any untoward symptoms whatever, and has remained in good health since.

21. **Diagnosis of Gastric Hypomotility.**—On the basis of clinical observation of 2,600 cases, Levy emphasizes that a rational test for gastric emptying should be based on a meal of ordinary bulk and complexity which the patient should dispose of in seven hours, and that the roentgen-ray test as commonly practiced is not sufficiently delicate for many clinical purposes.

22. **Aplastic Anemia.**—Schneider reports three cases. These three cases occurred in females. Two were definite asthenics, with a 30 gram thymus at the age of 26 in one. One was of normal habits. A definite history of a remote stomatitis or "cold in the head" was absent in two, but present in one. Between this and the fulminating onset with hemorrhagic symptoms there was a period of three and a half months of progressive anemia in this case, and this period of insidiously but rapidly developing anemia was also present in the first two cases. All three were free of clinical evidence of excessive blood destruction: pale sclera, pale urine and small liver and spleen. Viewed in the light of his findings and influenced by the postmortem observations of Engel and Hirschfeld, Schneider feels that proper emphasis should be placed on the fact of toxic marrow destruction, in a reconsideration of the terms by which this disease is known. Aplastic anemia implies congenital defect. Hypoplastic and aregeneratory imply poorly developed marrow readily failing on demand. Schneider suggests that a better term would be toxic paralytic anemia or toxic anhemopoietic anemia.

27. **Irritable Heart or Effort Syndrome.**—The inferences drawn by Smith and Bovaird from a study of fifty cases are summarized as follows: The irritable heart or effort syndrome cases constitute a symptom complex rather than a definite disease. It seems clear there is no definite disease of the heart, and they agree with Lewis that it is highly desirable to avoid any terminology which suggests that there is. The affection is not peculiar to soldiers but often precedes entry into service, though it may be exaggerated or in some cases produced by the active exercise or vicissitudes of the military life. Occupation in civil life is as much a result as a cause of the disturbance, in that men who know their weakness usually adopt an employment suited to it. In the great majority of cases no definite cause of the disorder is ascertainable. When such can be found it is most often an acute infection. Tobacco, alcohol, coffee and tea, though possible causes of aggravation of the symptoms, cannot be regarded as prime factors in the causation. Hyperthyroidism is suggested in some of the cases, but if present it is in a mild degree, and there seems no valid ground for regarding it as more than a contributory factor. In the light of the experience now available in the studies of Da Costa and the British commission it would seem wise to retain many of these patients in the hope of rendering them fit for duty of some kind. In view of their very limited usefulness in foreign service they should not be sent abroad. For the present, at least, the line of treatment must be that of progressive physical training as laid down by the British commission, which, even if it fails to produce satisfactory therapeutic results offers the best means of classifying the men as to their physical ability to perform military service.

28. **Lobar Pneumonia Treated with Antipneumococcus Serum.**—Camac's report deals especially with cases which were diagnosed clinically, bacteriologically and by postmortem as lobar pneumonia due to the pneumococcus cases which show, clinically, consolidation of part or of an entire lobe of the lung and due to the pneumococcus. The amounts of serum administered have varied between 50 c.c. and 600 c.c., with an average of 250 c.c. About 10 per cent. of the cases did not require serum treatment. Few patients came under treatment later than the third or fourth day, and many of them have been treated in the first forty-eight hours. Treatment was begun on the first clinical sign, without waiting for differentiation of type. For this purpose polyvalent serum was used. If the case showed Type I this serum was used, otherwise polyvalent serum was continued. No systematic blood cultures were made, but from the Rockefeller report and from his low mortality, Camac concluded that the early administration of serum prevented the development of or cleared the blood of pneumococcus organisms. In the few cases in which blood cultures were made this conclusion was supported. The rapid recovery of between 50 and 60 per cent. of all patients would indicate that the early use of serum tends to diminish the frequency of the complications. Dichloramin-T in chlorcosane 2 per cent. was used as a throat spray for attendants and with some of the cases. With the measles cases pulmonary complications were less frequent when this treatment was employed. About 50 per cent. of the cases showed signs of serum reaction. These ranged from simple erythema to the extensive urticaria, with general swelling

and joint pains. Some of the severer cases developed after 50 c.c. of serum had been given and others showed no reaction after 400 to 600 c.c. Manifestations appeared from twelve hours to fourteen days after administration. Only two cases showed any alarming features. Only one case presented symptoms of anaphylaxis. This was a case of asthma of unknown cause. Camac says that if more than 250 c.c. of serum are required and the temperature and toxic signs continue, complication by other organism should be suspected; like malaria when treated with quinin the pneumococcus is rapidly overcome by serum. Uncomplicated pneumococcus infection is a comparatively harmless and rarely a fatal condition.

42. **Study of Neurocirculatory Asthenia.**—The authors have studied fifty cases taken from all varieties of military service men deemed unfit for overseas duty and who, in contradistinction to the possible infectious and functional group, were selected because of the constitutional or preenlistment nature of their complaint. Measles, whooping cough and tonsillitis seem to have played the greatest rôles in the past history of these cases. Gonorrhea, pneumonia, scarlet fever, rheumatic arthritis and typhoid are next in frequency, and it is to this group of diseases that 22 per cent. of the patients dated the onset of their condition. Pain in the precordial region was the most frequent symptom complained of. Dyspnea on exertion, paroxysmal palpitation, giddiness, nervousness, weakness, sweating and flushing were next in order of frequency of occurrence. No one symptom predominated. Precordial distress, including dyspnea, pain and palpitation, nervousness, weakness and giddiness characterize the syndrome. Twenty-two per cent. gave a history of a sudden onset and these dated their condition from some previous illness, although this entire group had been more or less nervous and below par since childhood. In 78 per cent. the onset was gradual and the majority of these could give no definite reason or cause for their present condition. In most cases repetition of symptoms occurred with exercise, many others were due to emotional disturbances, and the remainder persisted constantly. Forty-seven out of the fifty cases under observation gave a history of nervousness and cardiac distress previous to induction into military service. Development of symptoms followed scarlet fever in one case and the severe strain of overtraining in two cases.

The majority of this group showed vasomotor instability as evidenced by alternating flushing, pallor, cold, cyanotic, clammy extremities and marked evidence of dermatographia. Fifty-two per cent. were robust and well developed, while 40 per cent. were rather slender, flat chested and showed poor muscular tone. One man had a right side empyema following pneumonia. Examination of the lungs showed no evidence of structural change. No one in the entire group presented evidence of structural cardiac change. The relative cardiac dulness was constantly within normal limits. Twenty-two per cent. had functional apical murmurs, while 28 per cent. had accidental pulmonic systolic murmurs. Two men showed impure first apical sounds, while two had a reduplication of the first sound. The response to exercise was fair in 40 per cent., good in 50 per cent., and poor in 10 per cent. Ten per cent. of the men had an apical systolic thrill palpable after exercise or excitement. A respiratory arrhythmia more marked in some than in others was present in all cases. Twenty per cent. of the cases under observation presented thyroid tumor to a greater or less degree. Ninety per cent. had chronic suppurative tonsillitis; thirty-two per cent. showed deviation of the nasal septum, 20 per cent. chronic sinusitis, while 8 per cent. gave evidence of otitis media. Sixty-six per cent. of the group presented no evidence of oral infection. Thirty-four per cent. gave positive findings of a degree indicating extraction.

All patients denied syphilis, while 24 per cent. admitted gonorrhea. Of the Wassermanns made only two (or 4 per cent.) were returned positive (+ +). No man presented an active gonorrhea. Rectal examination of the prostate showed 10 per cent. to be soft and slightly enlarged, 10 per cent. moderately enlarged, 6 per cent. small and nodular the, remainder normal. Only one case presented a tender and enlarged right seminal vesicle. Smears made of the expressed secretions following prostatic massage were all negative. Routine urine examination failed to reveal any unusual findings. Average blood counts made on the fifty men showed very little of interest. Definite evidence of psychasthenia was obtained in four men, one of whom was a religious fanatic. Two were definite neurasthenics, while four showed positive neurologic findings. Fifty-six per cent. of this group measured normal adult mentality, while 44 per cent. ranged from 8 to 15 years of age.

43. **Creatin Excretion in Fever.**—McClure believes that disturbances in the excretion of creatin, creatinin and uric acid during the febrile period of the acute infectious diseases are, largely, an expression of the effect of toxins on metabolism. These disturbances may continue into the period of convalescence. In the cases studied it was found that the increased excretion of uric acid almost invariably accompanied acute febrile states. It was usually associated either with creatinuria, or with disturbances in the output of creatinin. At times all three phenomena were present. McClure's experimental findings indicate that the loss of uric acid, creatin and creatinin by the body, during acute febrile conditions, is retarded by a high caloric diet rich in carbohydrates.

44. **Protein in Diabetes Mellitus.**—According to Mosenthal and Harrop the addition of an equal number of calories of protein, fat or alcohol to a low caloric carbohydrate-free diet in cases of diabetes mellitus results in the assimilation of considerable amounts of nitrogen when the protein is used, a favorable nitrogen balance in only occasional instances with fat, and no change in the nitrogen equilibrium when

alcohol is given. This would point to a high protein diet as the most advisable low-calory, carbohydrate-free diet by which to conserve the body tissues and furnish a maintenance ration for the diabetic.

45. **Hunger and Appetite in Pulmonary Tuberculosis.**—This study was conducted on six patients with early, moderately advanced, and far advanced pulmonary tuberculosis. None of the patients showed signs of peritoneal or intestinal involvement or had any gastric complaint other than loss of appetite. The outstanding fact in all of Meyer's observations is that contractions and stomach tonus are present. The association in these cases of hunger contractions with absence of hunger sensations suggests the possibility that these contractions are probably not registered in consciousness as such. In these cases the personal factor must be considered. Hunger contractions are present in some individuals, but instead of being recognized by the patient as such they are described as restlessness, headache and other symptoms.

46. **Electrocardiogram in Thyroid Disease.**—Very limited parallelism was found by White and Aub between the basal metabolism and the amplitude of the electrocardiographic T wave in a series of twenty-seven cases of thyroid disease. Auricular fibrillation, including the paroxysmal type, is not uncommon in hyperthyroidism as shown in this series by six out of forty-seven cases of hyperthyroidism (13 per cent.). Paroxysmal auricular flutter was seen in one case. Tachycardia, frequent hypertension and frequent tremor while at rest occurred in the cases of hyperthyroidism although not always parallel to the total metabolism.

48. **Tachycardia of Unknown Origin.**—The reactions to work of fourteen men with tachycardia, between the ages of 21 and 30, were observed by Barringer, on a number of occasions. Five men were classified as belonging to a severe type, chiefly because of their inability to perform amounts of work which normal men are capable of and because the performance of comparatively small amounts of work was accompanied by signs of distress-dyspnea, exhaustion or precordial pain. The pulse rates of the severe type of cases were all higher than normal and all showed greater increases immediately after work than do normal men after the same quantities of work. The pulse rate failed to return to normal inside of 120 seconds in sixteen instances when the heart was overtaxed; five times it returned to normal inside of 120 seconds, although the heart was evidently overtaxed; on nine occasions it failed to return to normal inside of 120 seconds, although the heart was not overtaxed. The curve of the systolic blood pressure showed several interesting anomalies when compared with the curves of normal individuals. "A delayed rise" in pressure following heavy work is an almost invariable finding in normal persons. In these persons, both of the severe and mild types, it is seldom found, and when present does not persist as in normal people. The great majority of these patients, both severe and mild, also show blood pressure curves following increasing amounts of work of what may be called a "diminuendo" type. The curves, instead of mounting higher and higher as they do in normal persons after increasing quantities of work, fall lower and lower. The smallest amount of work was followed by the highest curve and the greatest amount by the lowest curve. The various reactions to work which Barringer describes make it evident that, whatever the underlying cause of the circulatory condition in this small group of men may be, the heart's reserve power in each one was decreased.

49. **Effect of Thymus on Growth.**—Olkon succeeded in obtaining a reduction of weight in the male guinea-pig by the injection of thymus gland intraperitoneally. After the injection, well marked changes took place, namely, muscle spasm, dyspnea, and convulsion. The muscular spasms that occurred after thymus was injected appeared more severe and of longer duration than of either the muscle or of the tenth-normal sodium chlorid injected guinea-pigs. Some animals died after large doses of thymus injection. The general appearance of the animals in the thymus series was that of grave metabolic disturbances, emaciation, accompanied by dryness and roughness of their fur.

57 *Unusual War Psychoneurosis of Functional Loss of Sense of Smell. D. Wheeler.—p. 100.
58 *Fatal Case of Balantidiosis. F. B. Bowman.—p. 101.

55. **Diphtheroid Infection of Wounds.**—Sixty-three and five-tenths per cent. of open wounds examined by Janes and Thomas have shown diphtheroid organisms. Judging from those cases in which pure cultures were obtained, the authors believe that 6.4 per cent. of these open wounds showed infection with *B. diphtheriae*. Clinically, it is impossible to diagnose between diphtheroid and true diphtherial infection of wounds. A membrane does not necessarily indicate the presence of *B. diphtheriae* in wounds. It is not possible to distinguish between diphtheria bacilli and wound diphtheroids by morphological characters. Only by sugar reactions obtained from pure cultures can diphtheroid organisms be distinguished from true Klebs-Loeffler, and only after positive animal inoculation is it advisable to diagnose diphtheria in wounds. Flavine appears to have given better results than any other form of local treatment used in the hospital to which Janes and Thomas are attached. Hence it is considered advisable to administer diphtheria antitoxin in cases of diphtheria in wounds. The importance of giving a sensitizing dose in cases of war wounds due to their having received previous injections of serum is emphasized. If this rule is not followed severe anaphylactic reactions will occur in some cases.

57. **War Psychoneurosis: Functional Loss of Sense of Smell.**—Wheeler's case is interesting, because it demonstrates very clearly the four primary tastes. The man could only recognize things as acid, salt, bitter or sweet. He was quite incapable of recognizing any of his food—in fact, had lost that fine differentiation with which taste, and not smell, has usually been credited. He was unable to recognize volatile substances, such as strong ammonia, ether, oil of lemon, hydrogen sulphid, rosewater and oil of peppermint. Also a selection of different articles of foods were given to taste, such as cheese, butter, cabbage, potato, beef, jam, mutton, none of which were recognized. Considerable time was spent with the patient explaining his condition to him and assuring him that his sense of smell would be restored. A strong faradic current was applied to the back of the neck, and at the same time ammonia fortior was held under his nose, and he was instructed to tell what it was. At the end of one minute he recognized it as "ammonia." He next recognized oil of lemon with the aid of a weaker current.

58. **Fatal Case of Balantidiosis.**—This case occurred in a British West Indian soldier. Bowman says that a routine examination of the feces of men of the British West Indian Regiment disclosed that over 90 per cent. were infected with some parasite, and over 50 per cent. had hookworm disease. A trial with dilute solution of organic silver salts, both in balantidiosis and in amebic dysentery, is suggested.

69. **Metabolic Changes Induced by Administration of Guanidin Bases.**—The administration of guanidin to the animal body induces a condition of severe acidosis with the retention of phosphates, a decrease of calcium in the blood, and a hypoglycemia. These phenomena are also observed in tetania parathyreoprivia. Further, the symptoms and all other physiologic evidences in guanidin tetany are almost the same as in tetania parathyreopriva. Since the discovery of the large increase of guanidin bases in tetania parathyreopriva and idiopathic tetany, Watanabe suggests that perhaps the fundamental cause of tetany is the increased formation of guanidin nitrogen brought about by the disturbance of the function of the parathyroid.

73. **Effect of Placenta on Growth of Infants.**—During a series of experiments designed to show whether or not the maternal ingestion of desiccated placenta would have an effect on the chemical composition of the milk produced during the early stages of lactation, a comparison of the growth of the infants feeding on the milk produced during its administration with the growth of those subsisting on milk from mothers who had not been given the material, led to the idea that the feeding of this substance to the mothers had an effect on the rate of growth of their breast-fed infants entirely aside from the percentage change in the determined constituents. All patients were given desiccated placenta in the same dosage, e. g., 10 grains in capsules, t. i. d. From these, only those mothers were chosen whose parturition course was normal, and only the weights of those infants are utilized whose sole source of nourishment was the maternal breast. The diet of the mothers and the method of weighing of the infants were the same as reported in a previous paper on the normal growth capacity of infants. The effect of the ingestion of the desiccated placenta by the mothers on the rate of growth of the breast-feeding infants was at once apparent. In each group not only was the postnatal decline in weight less in amount, but also the gain in weight after the preliminary loss was greater in every case on every day than that recorded for the normal groups, the mean increase over the normal percentage change in weight on the thirteenth day being over 60 per cent.

There is no doubt that the rate of growth of breast-fed infants is enhanced by the maternal ingestion of desiccated placenta, for not only is the recovery to or over the initial weight generally more rapid, but the weight is almost uniformly greater. The growth capacity of infants subsisting on the milk produced during the administration of desiccated placenta is also increased. A large series of comparative measurements of the mammae of women taking and not taking the desiccated placenta, combined with a study of the time of onset of full milk production, failed to show either hypertrophy of the gland or an increased milk production on the part of those women ingesting the placenta material. Hammett concludes that there must be contained in the desiccated placenta some substance, or substances, capable of passing through the maternal organism with at least a part of its activity retained. Being secreted by the mammary glands, it is passed onto the infant in the milk, there acting as stimuli to growth.

Journal of Cancer Research, Baltimore

October, 1918, **3**, No. 4

77 *Occupational Cancer. H. C. Ross.—p. 321.
78 *Multiple Skin Metastases from Cancer of Internal Organs. N. Suzuki.—p. 357.

77. **Occupational Cancer.**—A recent government inquiry into pitch cancer at the briquette works in South Wales, England, disclosed some new clinical facts which make it appear that some definite if not specific, chemical rather than mechanical action is concerned in the causation of individual cancer. This led Ross to the investigation of other commodities the use of which also gives rise to cancer under certain conditions; and when all of them are examined collectively, there seems to be considerable evidence, both circumstantial and experimental, to show an association between certain chemical products of death and putrefaction contained in or produced by the commodities themselves and the onset of the disease. Ross investigated coal, tar, pitch, soot, napthalene, and other tarry commodities, anilin dyes, petroleum, grease, tobacco, betel nut, roentgen rays and radium rays, arsenic cancer and manure. This investigation showed that mechanical injury per se can play only a minor part in the predisposition to occupational cancer. Apart from the evidence in this respect given by the coal-tar industries, the action of petroleum, arsenic, manure, tobacco, etc., also demonstrates it; for some of these commodities are solids, some are liquids, and physically they differ a great deal in other respects. Yet they all seem to bring about the predisposition to malignancy in a somewhat similar manner, namely, by becoming impacted in the tissues, where, by giving rise to cell proliferation, they produce a warty condition. The warts usually ulcerate at their bases and drop off, leaving an intractable sore. It seems to be the edges of the ulcers that become epitheliomatous, and there appears to be a specific liability, when the industrial warts are untreated, for this to happen.

All of the active commodities examined, with one exception, are products of, or are derived from, the products of the death and decomposition of living matter, although such death may have occurred centuries previously. Coal and its derivatives, including paraffins, charcoal, tobacco, betel nut and manure, all have such a derivation; the one exception is arsenic, and that, being a powerful cell poison, may possibly produce the products of cell death and decomposition in the tissues. In this connection, Ross calls attention to the fact, that carcinoma seems more frequent, in general, at sites which are continually subjected to organic matter undergoing bacterial decomposition, such as the rectum, stomach and indeed the whole intestinal tract, mouth, uterine cervix, breast (chiefly in women who have borne children), prepuce, anus, scrotum, etc. In sarcoma, on the other hand, this does *not* apply, any more than does the age incidence; but with occupational epithelioma especially, given that the predisposing cause of the disease is present equally in different parts of the body, it is usually in that part which is the dirtiest or which is affected with open ulceration that the malignant condition supervenes. Decaying organic matter of all descriptions fertilizes living matter, and promotes cell proliferation, being used extensively for the growing of plants in agriculture. Up to a certain point, the more putrid the matter, the more pronounced is this fertilizing property.

There is a probability that the mischievous agents are organic nitrogenous substances of a group common to all the dangerous commodities. In the coal carbonization commodities, the fact that the coal is bituminous seems to be essential. Other analytic experiments showed that the active agents were nitrogenous substances produced by the decomposition of proteins, and several were isolated and proved to consist, among others, of some of the purin bases, such as creatin, xanthin and tyrosin. For convenience the name auxetic was given to these cell division producing agents. Auxetics undoubtedly prompt proliferation. Healing of a damaged site presumably is brought about by auxetics set free by the injurious agent, the amount of proliferation being in ratio to the amount of damage, a theory which seems to be a reasonable one. Experimentally, therefore, the action of the commodities can be explained by the auxetics or augmentors contained in the commodities themselves. They become impacted in the tissues, either in the hair follicles or the sebaceous glands, or perhaps in fissures caused by slight mechanical injury. Auxetics are dissolved out of the commodities and set up cell proliferation, giving rise to thickening and warts. The warts slough and drop off, leaving an open ulcer, in which the overprolific cells at the edge are prone to become malignant.

The malignant invasion, judging by clinical evidence, seems to be due to some additional factor, possibly connected with production of more kinetics, which excite ameboid movement and still further augment the proliferation. Auxetics are produced as age advances, the physiologic increase of cell death during senescence having this result. It is part of the working hypothesis that the predisposition to cancer during senescence may be due to a predisposition to cell proliferation caused by auxetics physiologically free in the tissues in general. But in occupational cancer, in addition to the auxetics produced by any mechanical or chemical trauma, there are also those contained in the commodities themselves which would produce, and which actually seem to produce, a greatly increased if not specific predisposition. An effort is being made, to prove the auxetic theory by destroying those substances in tar on a large scale, and observing whether th's destruction prevents the incidence of warts and cancer at the briquette works.

78. **Skin Metastases from Cancer of Internal Organs.**—An analysis is made of 110 cases which Suzuki collected from the literature, to which are added five cases that have come under his own observation.

81. **Irritant Properties of Chlorin Antiseptics.**—From experimental observations made on rabbit's ears with these solutions, Cullen and Taylor conclude that Dakin's hypochlorite solutions, of which the alkalinity is kept within the range of from 100 to 1,000 times the alkalinity of water (p_H of 9.3 to 10.2) by means of buffer salts, have practically the same degree of irritant action. Moreover, the manner in which these solutions are prepared, whether from bleaching powder and sodium carbonate, or from chlorin and sodium carbonate, and the type of buffer salt used, either carbonate or borate, have no influence on the degree of irritation. Solutions, however, that have an alkalinity less than that indicated by the end-point of alcoholic solution of phenolphthalein (p_H of 8.5 to 8.8), or greater than that indicated by the end-point to powdered phenolphthalein (p_H of 10.2), are intensely irritating. The sodium hypochlorite solution from which most of the calcium has been precipitated, and calcium hypochlorite solution seem less irritating than Dakin's solutions. The alkalinity in these unbuffered solutions is due mainly to the hydrolysis of the hypochlorite and is decreased as the hypochlorite is decomposed. This, rather than any specific action of the calcium, is probably the explanation of their lessened irritant action. It is also evident that the hypochlorite solutions maintain effective antiseptic concentration for about the same period of time, regardless of the manner in which they are prepared.

87. **Standardization of Antimeningococcic Serum.**—Experiments were made by Amoss and Marsh for the purpose of testing the reaction of protection against infection as a measure of potency of antimeningococcic serum. The results of these experiments were extremely variable and bore no relation to the quality of the serums as determined by the period of immunization of the horses from which they were obtained, or the indications of efficiency based on their employment in human cases of epidemic meningitis. The results also failed entirely to conform to the agglutination titer of the serum tested and to be affected by the different type forms of the meningococci. The authors regard the protective power for laboratory animals of the antimeningococcic serum as an unsuitable index of its value in human medicine and as inferior to the agglutination titer as a standard of potency.

118. **Empyema at Camp Doniphan.**—The high incidence of *Streptococcus hemolyticus* in the tonsils and nasopharynx of normal individuals during the period when streptococcic pneumonia and empyema were prevalent was observed by the authors. Blood cultures showed the presence of organisms late in the disease in grave cases only as a rule. A positive culture is a most unfavorable prognostic sign. The pleural exudate obtained from empyema cases from which hemolytic streptococcus was recovered showed a distinct difference in its physical characteristics in the majority of cases from the empyema fluid from which the pneumococcus was recovered. The streptococci recovered showed the same morphological and cultural characteristics, but the irregularity of serological reactions does not permit drawing definite conclusions as to their belonging to the same group. Agglutination reactions with patient's serum appeared to be of no diagnostic value because of irregularity of reaction with streptococci. Postmortem findings in cases presenting both pneumonia and empyema caused by streptococci showed in most cases distinct lobular pneumonia; in a number of cases the interstitial form of pneumonia, especially in the cases of patients who had been ill for a long time.

119. **Extra-Uterine Pregnancy Following Tube Resection.**—Tweedy urges the adoption of the catgut bougie as a means of keeping open the tube lumen. The critical period for closure of the tubes is comprised within the first three days after operation, while peritoneal exudation is poured out and adhesions are rapidly forming. Hence the catgut serves to effect the desired end and then is absorbed. The retention of the gut for many days in the tubes is harmful. The ciliated epithelium can hardly escape injury, and the irritative effect which it must exercise on the muscle layers of the tubes will be still more important. It seems to Tweedy certain that these muscle bundles by their peristaltic contractions must be the force which enables the ovum to reach the uterus and he feels sure that an arrest of their peristaltic wave is an important factor in the occurrence of tubal pregnancy. Silkworm gut, could it be used, would be free from the fear of exciting a chronic salpingitis but were it employed there must be some method perfected for its removal.

125. **Gonorrheal Empyema.**—Woodbery cites the case of a girl 8 years of age on whom he operated for a general peritonitis, probably due to a ruptured appendix. Drainage was instituted and the abdomen was closed without any further examination of the viscera, as the child was very ill and it was thought best not to prolong the operation. Following the operation the clinical course of the disease was that of a general peritonitis. On the sixth day after operation there were signs of a pneumonia or an accumulation of fluid at the base of the right lung posteriorly. On aspiration of the right chest there was obtained about 2 c.c. of a thick yellow pus. From this finding it was thought that the child had a right-sided empyema, a thoracotomy of the right chest was done. When the chest was first opened no pus could be demonstrated, but when the child was turned flat on her back a few cubic centimeters of pus flowed out of the wound. The child died in twelve hours from what seemed to be a respiratory failure. No necropsy could be obtained. On the second day after the first operation the child was found to have a profuse, yellowish vaginal discharge, and on examination of smears made from this there was found only the gonococcus, the diagnosis being made from the morphology and staining characteristics. Smears made from the pus obtained at the time of aspiration and at the second operation showed again the gonococcus. A blood culture made on the sixth day after the first operation, using special mediums, was negative. An attempt was made to grow the organisms seen in the pus from the chest but all the cultures remained sterile.

129. **Acute Infective Nephritis.**—The cases studied by Campbell and Rhea present a gross picture which is characterized by multiple, small or large areas of acute infection which may, and as a rule do, proceed to abscess formation. These areas are for the most part situated in the cortex. The infection is usually unilateral. Clinically, it is manifested by all the signs and symptoms of an acute illness. The lesions produced may resolve or may leave the kidney so damaged that complete recovery is impossible and may serve as foci on which further infection may develop. The commonest infecting organism is a member of the bacillus coli group, but other organisms as staphylococcus and bacillus typhosus may produce similar lesions. The infection is in most of the cases probably lymphatogenous, or hematogenous, and in some of the cases of bacillus coli infection, some abnormal condition of the gastro-intestinal tract, seems to play a distinct part. There are frequently no demonstrable lesions of the genito-urinary tract which might contribute toward the localization of infection in the kidneys. Treatment may be palliative, but operation may be necessary. If nephrectomy is required and is performed early in the disease the prognosis is good.

130. **Hematogenous Infection of Ovary.**—In Wiener's case the *Streptococcus hemolyticus* was found in cultures of the pus from ovarian abscess. The original source of the infection was not found.

134. **Paralysis of Upper Extremity.**—In Watson's case the three cords of the brachial plexus were compressed between the clavicle and the first rib by scar tissue, involving chiefly the inner and posterior cords. As the scar tissue was carefully dissected off, the plexus was found to be intact. To prevent the reformation of scar tissue, a fascia transplant from the patient's thigh was sutured about the inner and posterior cords. Five months after the operation the arm could be held at a right angle to the body. Sensation was nearly normal.

10. **Effect of High Carbohydrate Feeding on Nausea and Vomiting of Pregnancy.**—Duncan and Harding have proceeded on the assumption that in the early toxemias of pregnancy the dominant factor is a metabolic one. They have utilized the physiologic results of Imrie and of Mottram to connect the fatty degenerated liver found in postmortem examination of fatal cases of pernicious vomiting with the mild and moderate cases of vomiting. A temporary lack of carbohydrate supply has been assumed. In practically all cases of nausea and vomiting in pregnancy, acetone bodies were found in the urine. The authors have endeavored to correct the deficiency of carbohydrate supply by administering glucose or lactose, but mainly the latter, and supplemented this by a high carbohydrate diet. In this way they have successfully treated over seventy cases of nausea and vomiting in pregnancy, including several severe cases of the pernicious type. The patient is advised to rest, as far as possible, demands of housekeeping are limited, and any exciting factors removed. Meat and fatty foods are eliminated from the diet and their place is taken by a liberal supply of carbohydrate food, such as potato, rice, oatmeal, vegetables and fruit. In addition, one to one and a half quarts of a 5 per cent. lactose solution are taken daily by mouth. If this solution is not tolerated by mouth it is given by rectum. The actual amount of lactose to use is determined by constant urine examination. With the first sign of lactosuria, the dosage is diminished. When the nausea and vomiting are fully controlled, the amount of lactose is rapidly cut down to about 15 gm. per day. The patient may rapidly return to ordinary diet. All women so treated recovered very rapidly, and were delivered at full term of healthy children.

22. **Antiscorbutic Principle in Limes and Lemons.**—The antiscorbutic value of the juice of fresh limes (*Citrus medica,* var. *acida*) was compared experimentally by Chick and her associates with that of fresh lemons (*Citrus medica,* var. *limonum*) and was found to be distinctly inferior. Volume for volume of fresh lime juice possesses a potency of about one-fourth that of lemon juice. In one instance severe scurvy developing in a monkey on a diet containing a small daily ration (5 c.c.) of fresh lime juice was cured by an equal ration of fresh lemon juice. Preserved lime juice was found useless for the prevention of scurvy by the method employed. Experiments with preserved lemon juice are still in progress, but give promise of better results.

The experimental results are fully confirmed by a historical study of "lime juice" in connection with human scurvy. At the period when scurvy was eliminated from the British navy by its agency the term was used to express the juice of lemons, and it was not until the second half of the nineteenth century that the juice of West Indian limes was adopted in the navy and mercantile marine. The history of two Arctic expeditions, that of the Investigator, 1850, and that of the Alert and Discovery, 1875, was carefully investigated. The former, supplied with lemon juice, experienced remarkable immunity from scurvy during the first two years of great difficulty and privation; the latter, supplied with lime juice, suffered severely from scurvy at the end of the first winter spent in the Arctic regions.

23. **Case of Repeated Cessation of Heart Beat.**—Only one other case of arrest of the heart for so long as thirty seconds was found recorded by Poulton and Stewart. Their patient was a man, aged 67 years. During every two minutes the pulse completely stopped for forty-seconds. This sequence of events continued with regularity. There was no obvious abnormality about the heart. The patient was emphysematous and the apex beat barely palpable. There were no murmurs. When the pulse stopped no beat of the heart was audible with the stethoscope; nor was there any sound suggestive of auricular beats. No venous pulsation in the neck was observed. The man died with signs of cardiac failure.

29 *Aneurysm of Left Auricle. R. Lutembacher.—p. 434.
30 *Insufficiency of Left Ventricle. C. Laubry and L. Marre.—p. 458.

29. **Aneurysm of Left Auricle.**—Lutembacher published last year a case of this kind as a contribution to the study of bigeminal rhythm. In that case the cavity had a capacity of 400 c.c. It was not a simple retrodilatation secondary to a mitral lesion but an actual ectasia caused by grave and primary degenerative lesions of the wall of the auricle. It developed under his eyes from embolic obstruction of the afferent branches of the coronary artery. He now describes an additional case with a similar mechanism, but the wall of the auricle was already the seat of an old inflammatory process. The patients were young men; the first had a history of acute rheumatism, the other only a pleurisy without effusion in 1910. In the latter the aneurysm capacity was 500 c.c.

30. **Insufficiency of Left Ventricle.**—Laubry and Marre describe a case in which the slow and progressive insufficiency of the left ventricle had developed in consequence of the obliteration of the aortic orifice. There was no history of acute rheumatism in the case. The clinical picture had been extremely puzzling as the blood, passed through the narrow slit that was the only opening left, was too small in amount to induce any murmur. The necropsy findings are illustrated.

35 *Tendon Grafts. J. Nageotte and L. Sencert.—p. 448.

33. **Report of Research on Trench Fever.**—As mentioned in the Paris Letter, Dec. 21, 1918, p. 2090, Strong relates that 103 experiences on human volunteers have absolutely established that trench fever is a specific infectious disease caused by a filtrable virus transmitted naturally by the bite of the body louse or by urine or sputum. In commenting on this report, Roux remarked: "This work of the American Commission is a model by the ingenious and vigorous manner in which it was conducted. Thanks to the American soldiers who volunteered for the experiments, so that the nature of the disease to which their comrades were going to be exposed could be ascertained, everything in regard to the etiology and prophylaxis of trench fever was rapidly cleared up. The method employed by the American Commission and which consists in experimenting on men ready to volunteer for the purpose, has already afforded decisive certainty in our knowledge of yellow fever and other diseases. The risks which it inflicts on the patients who thus victimize themselves are paid for by the results by which all humanity profits." The other members of the commission, besides Major Strong, are said to have been Major Homer Swift, Major E. L. Opie, Capt. W. J. MacNeal, Capt. W. Baetjer, Capt. A. M. Pappenheimer, Capt. A. D. Peacock and Dr. D. Rapport.

34. **Bone Grafts.**—Dauriac reiterates that, with F. Albee's technic, bone grafts can be counted on to repair vast losses of substance, when otherwise amputation would be inevitable. He has applied this technic to all the long bones and with constant and equal success. The graft must always be taken from the subject himself, and the intervention must be postponed until all suppuration is long past, and a course of remineralization has prepared the bones for repair. The graft is taken from the sound mate, and is cut long enough so the ends fit far into sound tissue at each end, and the graft is fastened in place only with absorbable substances, never with metal. The access to the focus must never be through the old cicatrix, as this might rouse latent infection. Of equal importance is the warning not to immobilize the limb too long, but give it a chance for the normal dynamic functioning of the bone. According to Wolff's law, then, the bone will assume the shape and strength which its function demands. His long experience with this method justifies, he says, the highest hopes from it to uncripple the cripples, and he urges a special service for reconstruction of this kind on a large scale.

35. **Tendon Grafts.**—Nageotte and Sencert bridged gaps of 3 or 4 cm. in the tendons of the palmar side of the wrist by introducing six segments of tendons from dogs. The tendons had been kept in alcohol for a month. Each graft was fastened in place with two catgut sutures at each end. The aponeurosis of the brachialis was drawn over the whole and the skin was sutured without draining, and healed by primary intention. All the fingers can be completely extended, and flexion is almost complete for all except the middle finger which cannot be completely flexed.

48 Occupational Ridges in Skin of Back. D'Oelsnitz.—p. 942.

36. **Influenza.**—A similar article by Rénon and Mignot was reviewed recently in these columns. Thiroloix urges the importance of washing the hands before eating, and heating the loaf of bread in the oven the last thing before it is brought hot to the table. This sterilizes the outside from the contacts with different hands. The beverages should also be taken hot for the same reason, except wine from the bottle. All raw foods should be avoided during "flu" times. We should realize that every object and the air surrounding an influenza patient are liable to have been contaminated by droplets from him. Netter and Josué among others advocate suprarenal treatment, as a number of the symptoms in influenza reveal suprarenal insufficiency. Sergent declares that suprarenal treatment is usually too timid. It should be given in fractional doses, but up to 5 or 8 mg. is none too much. The subcutaneous or intramuscular route is preferable to ingestion. He suggests that instead of using convalescents' serum there might be advantage in transfusing whole blood, citrated, from the convalescent, and not the serum alone. This has proved very effectual in grave measles in Ribadeau-Dumas' hands. He intends to try it in influenza.

38. **Traumatic Pulmonary Tuberculosis.**—Descos' patient was a healthy aviator who did not seem to feel any evil consequences for about a month after a fall of 90 feet, hitting the left chest. Then fever developed and acute pleuropulmonary tuberculosis. There was little expectoration but tubercle bacilli were found in the sputum, and the seventh week acute pulmonary edema proved fatal. *Necropsy* disclosed all recent lesions.

39. **Limits of Radioscopy of the Lungs.**—Mantoux placed on the chest a piece of tuberculous tissue from a cadaver and found that even quite thick and large pieces of such tissue cast no appreciable shadow in radiographing persons of average build. The stethoscope may reveal lesions that escape the roentgen rays, and in any event the absence of roentgen findings cannot be accepted as conclusive demonstration as to the certain integrity of the parenchyma of the lung and of the pleura.

42. **Influenza.**—Merklen emphasizes that in his district influenza was mild for two or three months. Then it became virulent and now (in October) it is extremely virulent. Very few cases are observed in children, and the fatal cases are in the robust young people or older ones with already damaged lungs. Hot packs around the chest and fixation abscesses aid in subacute cases still capable of reacting. Venesection

should be tried in cases with cyanosis and pulmonary edema, but it is not so useful *for toxic processes* as for vasomotor disturbance.

43. **Evolution of the Ameba.**—*Job* and Hirtzmann report that the ameba of dysentery, such as we see it in the stools, is only one phase of the evolution of the parasite. The pathogenic phase is an intracellular parasitism. The young protozoon penetrates into a liver cell: *at that time it is* reduced to a homogeneous nucleus. The nucleus of the liver cell enters into karyolysis, the protoplasm develops vacuoles and tends to disappear completely, the parasite gradually supplanting its host entirely.

44. **Sign of Sciatica.**—Rimbaud noticed that in about 70 per cent. of his cases of surgical lesions of the sciatic nerve and in 25 per cent. *of medical sciatica* cases, the groove each side of the Achilles tendon seemed to be effaced, flattened out. It seems to be a manifestation of hypotony *on the* part of the muscles in which the Achilles tendon has its point of attachment. This useful objective sign of sciatic disease can be determined by placing *the subject as if to* elicit the Achilles tendon reflex.

46. **Acute Leukemia with Spirochetosis.** — The case described by Sicard and his co-workers differs from the other cases of "French spirochetosis" on record in that the clinical picture was that of a subacute leukemia, fatal in five months. The patient was a clerk *of 46. and spirochetes* were found *in the* urine *during life* and in the liver and kidney after death. Inoculation of guinea-pigs with blood and urine was negative, but the serum agglutinated *promptly the* icterohemorrhagic spirochete. The health had been normal before: no history of syphilis or malaria. The first symptoms were impairment of vision, loss of appetite, insomnia and digestive disturbance. Necropsy showed the liver in fatty degeneration but the kidneys and lungs were approximately normal and there was no enlargement of glands.

55. **Tetanus After Section of Spinal Cord.**—The *projectile* had pierced the spine and the paraplegia was of the total section type. The thirty-second day the legs developed severe tonic and clonic contractions with trismus and sweating of the upper part of the body. Death followed in four days, necropsy confirming the anatomic section of the cord at the eighth dorsal segment. The case reaffirms the independent activity of the lower part of the spinal cord.

56. **Epidermitis.**—Gougerot warns of the danger of chronic epidermitis as liable to set up erysipelas, etc., if the skin is incised at a point thus affected.

Presse Médicale, Paris

Nov. 11, 1918, **26**, No. 62

58 *Crippled Digestions. M. Labbé.—*p.* 569.
59 *Open and Closed Pulmonary Tuberculosis. C. Mantoux.—*p.* 570.
60 *Radical Cure of Genital Prolapse. S. Mercadé.—p. 573.

58. **Crippled Digestions.**—Labbé discusses how to exclude actual anatomic disease or definite physiologic upset, and recognize what he calls crippled digestions, and determine the type *of* the latter. The treatment *required* differs from case to case, but good hygienic conditions give the digestion the best chance to right itself.

59. **Open and Closed Pulmonary Tuberculosis.**—Mantoux analyzes the later course in 2,000 men with or suspected of pulmonary tuberculosis that have passed through the *service de triage* at the Laennec hospital. He emphasizes the differences between "open" tuberculosis, *that is, the* cases with ulceration from the start, and those with healed ulceration, and those that have not presented ulceration, that is, the "closed" cases. The *tuberculosis* is progressing but there is *no ulceration.* The *affection* is relatively mild; none of the men in this group have died. He emphasizes that radiography *gives much* more instructive findings than radioscopy. In conclusion he refers to Heise and Sampson's recent description *of a peribronchial form,* rarely opening into a bronchus, *and suggests* that this may be the habitual anatomic form of nonulcerative pulmonary tuberculosis.

60. **Treatment of Prolapse of Female Genital Organs.**—The principles of Mercadé's *method* have already been described *in these* columns (Nov. 9, 1918, p. 1615). It is based on the assumption that with a tendency to prolapse it is the roof of the *anterior vagina that sags first* under the strain from the abdomen. The bladder sags next, and the uterus not until after this. He cuts a lozenge *out of the roof* of the anterior *vagina,* and then detaches *the bladder* very carefully, pushes it up, and makes a solid support for it by *suturing the levator ani* muscles together along the median line. *Six large illustrations* show the various steps of *the* method, *as he has* applied it in seven cases, all radically *cured* by it.

65 Symptoms of Incomplete Ileus. J. Fiévez.—p. 331.
66 Access to Splenic Flexure. *J. Fiévez.*—p. 332.
67 *The Wassermann Reaction. Carle.—p. 333.
68 Hysteria *Simulating Epilepsy.* Bernheim.—p. 335.

61. **Intracranial Hemorrhage in the New-Born.**—*Vignes* declares that although the prognosis may not be absolutely fatal, yet the sequels in the survivors justify the most heroic measures to clear out the *extravasated blood.* He describes the symptoms liable with hemorrhage above and below the tentorium. Operating without delay and reducing the loss of blood to the minimum will aid in keeping down the mortality which to date is 50 per cent. Lumbar puncture may be useful, repeated two or three times a day if it brings blood. Simmons incised the fontanel and dura, and evacuated the blood rapidly in this way in some desperate cases. If the skull is to be opened, this should be on the side opposite the arm presenting the most pronounced convulsions. The base of the skull flap should be about 5 cm. across, and every vessel that has to be severed must be ligated with fine silk. If the *blood* is *not* clotted, he advises leaving a drain for a day, puncturing if hemorrhage in the ventricle is suspected. If the brain is bulging, without hemorrhage, bilateral trephining will relieve the pressure. If the injury is below the tentorium, the child is quiet and does not scream *but is somewhat* cyanotic and presents nystagmus. As the blood flows down the spinal subarachnoid space, there is stiffness of the neck, and diffuse rigidity, with erection. Lumbar puncture always shows blood and the fontanels do not bulge. *With the subtentorial* hemorrhage, *Cushing's occipital* incision is called for.

62. **Fracture of the Clavicle.**—Hidden expatiates on the advantages of a device which draws the shoulders outward, backward and upward, thus immobilizing the fractured clavicle in the best position for repair. This is *accomplished* with two round metal rings which fit over the *shoulders* and are tied together at the back and also at the *front.* These rings can be made hollow or they can be made of wire *with* an envelope of *plaster.* They are wound with cotton and the *force* is applied in tying the rings together at the back. The arms are left entirely free with this contrivance, but it is better to keep the patient in bed the first day. The *rings* are bent a little to fit the parts, as is shown *in the* illustrations.

67. **The Bordet-Wassermann Reaction.**—Carle has been *investigating* this reaction in connection with *the* date of contamination. He *found* that it is rarely positive *before*

the fiftieth day from the date of infection. Hence a dubious or negative response before that must be regarded with suspicion. Even before the fiftieth day, however, there is usually some more or less slight positive response that warns to be on the alert. A persistently negative response, on the other hand, is strong presumption that the genital lesion is merely a soft chancre. In about one case in every twenty-six in his experience, the response persisted negative until the roseola appeared—then veered to positive. In the second phase of untreated syphilis, the Wassermann reaction is most reliable, but treatment should never be suspended in this stage because the Wassermann reaction has become negative. In any event, he reiterates, tentative specific treatment should be given a trial in all dubious cases, regardless of the Wassermann findings.

Revue Médicale de la Suisse Romande, Geneva

October, 1918, **38**, No. 10

69 Mongolian Idiocy and Quadruped Gait. P. Bourdillon.—p. 585.
70 *Menstrual Psychosis. F. Naville.—p. 591.
71 *Stones in the Appendix. F. Blanchod.—p. 599
72 *Ileus from Cherry Stones. A. Kotzareff.—p. 611.
73 Influenzal Paralysis of Soft Palate. L. Du Pan.—p. 613.

70. **Menstrual Psychosis.**—Naville reports a case of "dream delirium" in which the erotic delirium was accompanied by melancholia, ideas of suicide and a tendency to mania. The young woman was of the microcephalous type, with a tendency to migraine and dysmenorrhea, and inability as a child to keep up with her class in mathematics. Cases of this kind are often mistaken for dementia praecox, but we should be careful not to regard every acute mental incident in a person naturally below par or a psychopath as necessarily the indication of a psychosis with a progressive course. In this case measures to promote menstruation and regulate the functions generally were soon followed by subsidence of the tendency to psychosis, and the young woman has had no recurrence since, during the six years to date, although she is still childish and emotional.

71. **Calculi in Appendix.**—Blanchod was examined with the roentgen rays forty-five hours after beginning of symptoms which were explained by the shadows of two calculi which projected above the crest of the ilium. The urine was normal, which exculpated the ureters, suspected at first. The calculi were found in a retrocecal pus pocket, and the appendix was totally gangrenous. Bronchitis followed the operation, and then both parotid glands suppurated, discharging through the ducts of Steno. The parotitis seemed to act like a fixation abscess and prompt recovery followed. As a boy of 13, he had been kept in bed for three weeks with appendicitis but the appendix had never given any signs of its existence otherwise. If he had known he was harboring two calculi in his appendix he would scarcely have ventured on the trip to India as inspector for the Red Cross of prison camps in the Orient. He was far in the interior of India when intense pain developed in the right flank. He remarks that his case reaffirms the frequent difficulty of diagnosing appendicitis with stones. J. Roux has reported nine cases in seven of which the roentgen rays revealed the stones. In one of the cases the stone in the appendix induced a set of symptoms exactly like those from a stone in the ureter. In another case the stone was not discovered until investigating to learn why the fistula from the operation on the appendix refused to heal. In another case the supposed stone must have been the shadow cast by a calcified gland in the ileocecal angle. Radiography was constantly negative in one case until the fourth application, when the calculus cast an unmistakable shadow. In another case the calculus found in the appendix at the operation had never cast any shadow. The case in Blanchod's own person is the fourteenth on record, he says, in which the calculus was revealed by the roentgen rays before the operation.

72. **Ileus from Cherry Stones.**—Two tumors with a tender zone between, all in the descending colon, proved to be an accumulation of 712 cherry stones. No cherries had been eaten for several months, and microscopic examination at necropsy revealed incipient malignant disease. The latter had probably interfered with normal peristalsis.

74 Treatment of Anemias. W. Löffler.—p. 1521.
75 *Ethyl-hydrocuprein (Optochin) Amaurosis. M. Ujiie.—p. 1556.

75. **Amaurosis Under Ethyl-Hydrocuprein.**—Ujiie reports the case of a girl of 10 who died in the third week of a pneumococcus peritonitis with sudden stormy onset in the midst of health. Complications on the part of the lungs had followed a laparotomy which had confirmed the diffuse suppurative peritonitis. The child was then given six doses of 0.2 gm. ethyl-hydrocuprein (optochin) at four hour intervals. Two days later there was total amaurosis which persisted till death, only slightly receding toward the last, allowing perception of light. The microscope showed edema and vacuoles in the retina, with swelling and beginning destruction of the nerve fibers in the optic nerve. Necropsy of some pneumonia patients who had taken optochin without disturbance in vision showed the optic nerve entirely normal. Uhthoff has also reported recently two cases of optochin amaurosis in men of 28 and 45 with extensive destruction of the medullary sheath of the optic nerve as evidenced by Marchi staining. All the findings readily explain why in one case there may be complete and integral restitution while in another permanent damage may result.

Policlinico, Rome

78 *Radioscopic Records. V. Stenico.—p. 1057.
79 Criminal Abortions. E. Santi.—p. 1057.
80 *Silver Nitrate for Mustard Gas Lesions. G. Viale.—p. 1061.

77. **Autoserotherapy in Influenza.**—Meille reports favorable experiences with subcutaneous injection of 1 or 2 c.c. of the patient's own serum, taken from the blood drawn twelve hours before and set aside in a slanting test tube. The complications of the influenza did not seem to be modified, but the general condition showed marked improvement. Saline infusion proved a useful adjuvant, with venesection unless the heart action was too weak for this.

78. **Radioscopic Records.**—Stenico places a sheet of glass over the screen and draws on this the outlines of the shadows cast on the screen. It is easy to get a copy of this by applying a moistened paper, a sheet of cardboard, and a bag of sand on top, as a letter is copied in a letter press. Two or even three of these copies can be made, and they prove valuable records of the cases.

80. **Mustard Gas and Silver Nitrate.**—Viale was unable to confirm Amantea's statements in regard to the effectual neutralization of yperite by silver nitrate. He experimented on the human while Amantea's research was done mostly on animals. It did not seem to impede or limit the injury from the mustard gas, but it had an unmistakable action in promoting the healing process. Viale's experience also teaches the necessity for leaving the lesions open to the air. The fumes held in by a dressing cause new lesions.

81 *Nature of Febrile Pandemic. U. Baccarani.—p. 870.
82 *Epidemic Meningitis. R. De Nunno.—p. 872.
83 Emetin in Rebellious Malaria. E. Carlino.—p. 875.
84 *Febrile Pandemic. Referendum. Ceconi and others.—p. 876.

81. **Nature of Influenza.**—Baccarani is inclined to believe that influenza is a polybacterial epidemic. No one germ is responsible for it. The germs causing it have had their virulence suddenly enhanced by some mysterious influence, electric, atmospheric or telluric, some sudden modification of the physical and chemical ambient in which mankind lives. Besides the bacteria, the pathogenic factor is probably a complex of many minute causes. These of course are beyond our ken. Too little is known yet of these *cyclonoses* for us to hazard any serious contributions to this important subject.

82. **Laboratory Inferences in Meningitis.**—Nunno's tabulations are not published with this article but will accompany the reprints. They are said to show the various findings in

the cerebrospinal fluid as compared with the clinical course of epidemic meningitis. The urea content seems to have a bearing on the prognosis, but not the albumin content, although the latter may be useful in differentiation from tuberculous meningitis. Determination of the chlorids throws light on both diagnosis and prognosis, as also the content of substances reducing the Fehling reagent. When the fluid is limpid or only slightly turbid, epidemic meningitis is indicated by a content in albumin close to 3 per thousand; of chlorids above 6.09 and below 7.32 per thousand, and the reducing substances diminished or lacking. A favorable prognosis is indicated by chlorids above 6.43 and urea below 0.24 per thousand, and the reducing substances not too low. The Vincent-Bellot precipitation test is valuable for the differential diagnosis. It is more reliable when done with the zonal technic. If the meningococci are found loose in the fluid, especially when associated with other germs, the outlook is extremely grave. As the meningococci are frail, they are liable to die when sent to a distant laboratory for identification. The diagnosis can usually be based on the precipitation reaction and the chemical tests mentioned above so that the specific antiserum can be injected without delay. Nunno regards a limpid fluid at the first examination—before serotherapy has been attempted—as a very unfavorable sign.

84. **Quinin in Influenza.**—Cecconi relates the significant fact that in a town in Italy where malarial soldiers are segregated, there has not been a case of influenza among the malarial inmates of the four hospitals, although the physicians, nurses, clergy and others connected with the hospital had the disease in epidemic form. Is malaria incompatible with influenza? he queries, or does the quinin the men are taking protect against it?

91 *Defective Development of the Blood. G. Pittaluga.—p. 513.
92 *Mercurial Injections in Children. E A. Sainz de Aja.—p. 530.
93 Pouch in Buttocks Opening into Rectum. Juaristi.—p. 533.

91. **Defective Development of the Blood.**—Pittaluga's classification of blood diseases has been widely adopted, especially his term hemodystrophies. This represents the group of cases in which the biochemical abnormalities predominate over the histopathologic, and a neuropathic factor is manifest, either directly or through the mediation of the glands with an internal secretion. A hereditary influence is also apparent, congenital and familial factors intervening either directly or indirectly. The group contains the so-called hemorrhagic diatheses, purpuras, scurvy, hemophilia, paroxysmal hemoglobinuria, and hemolytic jaundice. These hemodystrophies may be classified further as frankly congenital or inherited, such as hemophilia; those depending on dietetic or toxic action or deficiencies, such as scurvy, and those due to some virus. In hemophilia there seems to be both a delay in the coagulation process and a special fragility of the walls of the vessels. Pittaluga has encountered a number of cases in which inherited syphilis was clearly a factor in this generalized lesion of the media and intima coat of the vessels, both aplasia and degenerative processes being evident. The influence of inherited syphilis in the pathogenesis of the exudative diathesis and the eosinophilic diathesis has not been appreciated hitherto. The clearing up of these problems is in the hands of the pediatrists. They can investigate the heredity and bring light to bear on the etiology of many constitutional diseases, and above all on what may be called the hemodystrophic states. Polycythemia and chlorosis have their foundations laid before puberty, although they may not develop until later. All these hemodystrophies testify to the close connection between the blood-producing organs and the endocrine system, and to the transmission of this connection to the offspring, along with its reflected alterations in the nervous system. All this field lies open to the pediatrists more than to any one else.

92. **Mercurial Treatment of Infants.**—De Aja lauds the efficacy of a few harmless injections of mercuric benzoate (benzoato de mercurio), 1 mg. per kg. of weight, twice a week, as a means of treating syphilis in infants. It has a dual action, both as mercury and as a benzoate, modifying favorably any lesions in the liver and respiratory apparatus. For infants over a year old, the injection can be of 0.5 to 1 cg. twice a week. He makes the injection in the back, near the spine, as deep as possible, massaging afterwards. Of course this technic is for exceptional use only; inunctions are more convenient, but it has its special field when other methods fail and arsenical preparations cannot be used, or when mercury is required besides.

97 Further Research on Gregarinas. XII. C. F. Pinto.—p. 321.

96. **Trichomoniasis.**—Paranhos has been testing various means to rid the bowels of the *Trichomonas hominis* which is not rare in his region in Brazil. Flushing the intestines with a 1 per thousand solution of iodin proved effectual but too inconvenient for general use. A complete cure was realized, however, without untoward by-effects, by a course of methylene blue, 0.2 gm. taken in a capsule every morning, fasting. This amount is tolerated for many weeks, and a sodium sulphate purge, once a week, shows when the parasites have disappeared. All his patients were cured in eight weeks, and none of the parasites have been found in the stools during the months since. Castellani has reported similar success with it in such cases.

102 Effect of Chloroform on the Heart. E. Fernández.—p. 205.
103 *Idiosyncrasy to Antipyrin Salicylate. E. P. de Bellard.—p. 208.

100. **Ambard's Ureosecretory Coefficient.**—Razetti reaffirms that not even Ambard's formula has proved the long sought index of conditions which will permit general anesthesia and a major operation without special risks.

101. **Campaign Against Venereal Disease.**—These communications relate what has been done in this line in other countries, and propose measures to be adopted in Venezuela. At the close of the discussion the Academia Nacional de Medicina voted resolutions calling on the National Public Health Service to organize free dispensaries for the venereal diseases, separate for the sexes, with private and public conferences, instructions in various centers, circulars, etc., to educate the public to apply to these dispensaries. If these measures fail, extreme measures of compulsion may become necessary. Medical inspection of places and centers where venereal diseases are known to be prevalent, is also advised, and the discreet gradual registration of all prostitutes. The resolutions concluded with the offer of the individual and the collective aid, private and official, of the members of the Academia de Medicina, to help in the prophylaxis of venereal diseases.

103. **Idiosyncrasy to Antipyrin Salicylate.**—De Bellard prescribed a few doses of antipyrin salicylate, each 0.75 gm.,

for a colored man of 40 who complained of pains in certain muscles. The first dose caused burning and edema to such an extent that it seemed that a caustic had been taken by mistake. By the next day the lips and mouth looked as if lined with yellow cotton, and in two days the tissue affected was cast off, the cheeks, lips, gums and pharynx being thus denuded, and the whole course of the esophagus smarted and there was also pain in the epigastrium, whenever the man took any water or milk, the only things allowed. The ulceration was apyretic and healed in the course of two weeks without leaving a trace. Two years before the man had had a similar experience, also after a single dose of antipyrin salicylate, but the connection with the drug was not suspected at that time. To convince the man that the trouble was in him and not in the drug, Bellard and the man's wife took some of the powders before him, with no appreciable by-effects.

106 *Pathogenesis of Alcohol Intoxication. V. Ducceschi.—p. 125.
107 *Plastic Motor Operations. G. B. Arana.—p. 126. Commenced in No. 12, p. 113.
108 Case of Senile Dwarf Growth. (Progeria.) J. Orrico.—p. 133.

104. **Spastic Closure of Gastro-Enterostomy for Pyloric Ulcer.**—Udaondo reports two typical instances of this. The gastro-enterostomy had put an end to years of suffering but in time the new opening contracted spasmodically so that the old train of symptoms returned. They are the only instances of the kind he has encountered in seventy-one operative cases of pyloric ulcer, although a number of them presented the clinical picture of vagotony with gastric hypertony. In his first patient, a man of 47, an exploratory operation and gastro-enterostomy on two different occasions gave relief for five years, and then the symptoms and radioscopy showed complete occlusion of the new opening. Under a course of atropin, clinically normal conditions were restored for a year when he succumbed to pneumonia. Necropsy showed one of the new openings entirely permeable. In the other case the man of 34 presented miosis, slight bradycardia, hyperchlorhydria and colonic spasm. Under daily injection of 1 mg. of atropin, all disturbances ceased in two days except for a slight burning which yielded to an alkaline. In less than two weeks the gastro-enterostomy opening was working perfectly, and there has been no further disturbance during the months since. In conclusion Udaondo remarks that the vagus and sympathetic systems are not so strictly selective as some believe. They might react indiscriminately to certain other drugs.

105. **Effect of Alcohol on Nerve Centers.**—Jones gives illustrations of the histopathology of alcoholism. Alcoholism may be assumed, he remarks in conclusion, when besides the lesions of chromatolysis in the third layer of large pyramidal cells of the brain, there is dilatation or congestion of the capillaries, thickening of the meninges, without leukocyte infiltration, and small hemorrhages.

106. **Pathogenesis of Alcohol Intoxication.**—Ducceschi has been continuing his research on the cholesterol and lecithin content of the blood of dogs kept under the action of alcohol. He here announces that besides the unusually high content of the blood in cholesterol and lecithin, the neutral fat of the blood is also increased. There seems to be an actual mobilization of the lipoids, a lipoidolysis, which may be a defensive function on the part of the organism.

107. **Plastic Motor Surgery.**—Arana reproduces a large number of illustrations of what has been done in this line in Italy and elsewhere, and describes five cases in which he has operated to provide volitional control of the artificial limb or prosthesis. There are forty-one illustrations in all. He relates that since the legislation on workmen's compensation two years ago, the amputated at Buenos Aires who would be proper subjects for this kinematic surgery, refuse to permit any operation which might reduce their incapacity as this would cut into their pension. In one of the cases the "key loop" was unintentionally provided. The hand had been amputated at the carpometacarpal articulations, and the carpus acts like a hook to grasp objects. The play of the flexor and extensor muscles gives here a power of 20 kg. with an excursion of 3 cm. In another case the arm had been amputated at the elbow at the age of 3, and the man of 33 now has powerful muscular control of the stump, the olecranon being drawn up by the muscles to form a useful hook or key with which objects are seized. He steadies them by holding them against his chest. Excursions of 5 cm. are possible. Arana tried to devise prosthetic apparatus to utilize these kinetic forces, and has succeeded in this case in providing an artificial hand and arm which is able to lift 2.5 kg. and is capable of excursions up to 2 cm. One illustration shows him lifting a glass of water with his "kinematic hand." The amputations in the other cases were in the upper third of the arm or shoulder. An Indian plastic flap was used to cover the pectorobicipital loop in each case.

110 *Epidemic of Diphtheria. G. Marquez.—p. 30.
111 Metabolism in Diabetes. E. Gomez.—p. 37.

109. **Prophylaxis of Tuberculosis.**—Angel relates that the first legislation in regard to tuberculosis in Colombia dates from 1916. The public health service was then reorganized and a subsidy of $30,000 was appropriated to establish antituberculosis dispensaries in various centers of population where the local authorities aid in the work. The law provides for isolation of the tuberculous in special departments of hospitals and prisons. Angel insists, however, that the best prophylaxis of tuberculosis is by medical inspection in the schools, and segregation of the weakly and backward in a special school where they could be trained in body and mind to approximate normal. If legislators realized the importance of these schools for bringing those predisposed to tuberculosis safely through the dangerous years, great progress would be realized in stamping out tuberculosis at the source. It requires the teaching of hygiene by physicians, individual effort, and direction by the state. He speaks as if medical inspection of schools in Colombia had not yet been realized, but this he regards as the keystone of progress in this line, especially when supplemented by special schools for the abnormal.

110. **Diphtheria at Bogotá.**—Marquez remarks that diphtheria in Colombia does not seem to be as grave a disease or as contagious as elsewhere, but it has been growing more contagious in recent years. One peculiarity of diphtheria in Bogotá has been that it seemed to be restricted to well-to-do families. He knows of only three cases among children of the dispensary class.

119 Spinal Anesthesia. G. Palacios.—p. 377.
120 *Comparison of Pubiotomy and Symphysiotomy. T. A. Chamorro.—p. 378.

117. **Cataphrenias.**—By this term Austregésilo defines a state of mental debility of the dementia type. It differs from dementia, however, in that it may retrogress and complete recovery ensue. He has had a number of patients of this type, the diagnosis wavering between dementia praecox, chronic mental confusion and manic depression, and insanity of the confusional or stupid form, but by the end of six months to three years the marked improvement or complete cure upset all his theories as to the nature of the psychosis. He describes a few cases, all in young men and women, of this acquired psychic deficit which may retrogress or may progress to actual dementia praecox, chronic mental or catatonoid manic-depressive insanity.

120. **Pubiotomy and Symphysiotomy.**—In this eighth installment of Chamorro's clinical and surgical comparison of these operations, he discusses the technic for the wholly and partially subcutaneous method, and warns of every point liable to cause difficulty. He also describes how to manage the case to ensure spontaneous delivery.

122. **Visual Organs of Insects.**—Cajal's research has convinced him that the facetted eyes of insects serve for perception of color and for vision during the day, while the ocellus eye is an organ hypersensitive to light, and is depended on to guide the insect in the dark.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

Oct. 12, 1918, **2**, No. 15

123 *Racemose Aneurysm on the Head. W. Noordenbos and R. de J. de Jong.—p. 1224.
124 *Gastro-Enteritis of Unknown Origin. K. Wassenaar.—p. 1235.
125 Electricity in Examination of Children. H. A. Stheeman.—p. 1237.
126 Case of Habitual Subluxation of Knee. J. H. Engelkens.—p. 1241.

123. **Racemose Aneurysm of the Head.**—The case reported was remarkable in the extent of the area of the scalp covered by the cirsoid aneurysm, also in the successful operation, and in the microscopic examination of the aneurysm tissue immediately after its removal. The patient was a man of 34. At 17 he had applied for excision of a small tumor on the previously normal scalp, but as the tumor was found pulsating, the excision was refused until, at 34, the tendency of the aneurysm to bleed spontaneously compelled intervention. The operation was done in one sitting after ligation of the external carotid and frontal arteries on both sides, under local anesthesia, with epinephrin, the patient seated. Catgut was passed around each of the afferent vessels and tied over a roll of gauze. The pictures show ten of these little rolls of gauze on one side of the scalp, one at the root of the nose, one exactly opposite at the back of the head, one just above the ear, and the others scattered in series along the course of the arteries. Inside this crown of gauze rolls the main aneurysm was excised, the skull and periosteum being found normal. There was no hemorrhage except from two small arteries in the periosteum, which was easily controlled. There was no fever or suppuration, and the gauze rolls and catgut were removed the ninth day. By this time the whole network of vessels on the scalp had subsided. A few weeks later the defect in the skull was covered with Thiersch flaps, the whole intervention a complete success. In some of the cases on record the attempt to save part of the scalp in the aneurysm region proved disastrous as the tissues are pathologic and friable. Several who tried to operate without the preliminary ligation of the carotid had grave hemorrhages. In one case the patient was unable to leave the hospital for seven months. The common carotid cannot be ligated for the purpose. After removal of the main tumor in the case reported, the afferent vessels had disappeared without a trace by the ninth day.

124. **Epidemic of Gastro-Enteritis.**—Wassenaar describes an epidemic of abdominal pain and other gastro-intestinal disturbances affecting 500 of the 6,500 Belgian refugees in a certain camp. Only five died, but their deaths were sudden. No cause could be discovered unless the whole trouble is accepted as a gastro-intestinal form of influenza.

Hygiea, Stockholm

Oct. 31, 1918, **80**, No. 20

127 Successful Operative Case of Cardiospasm with Dilatation of the Esophagus. E. Lindström.—p. 1169.

Ugeskrift for Læger, Copenhagen

128 *Habitual Constipation VII. T. E. H. Thaysen.—p. 1729. Conc'n.
129 *Influenza and Pulmonary Tuberculosis. G. E. Permin.—p. 1739.
130 *Influenza and the Copenhagen Medical Society. V. Bie.—p. 1741.
131 *Fatal Cocain Poisoning. W. Møller.—p. 1743.

128. **Habitual Constipation.**—Thaysen concludes his seventh study of this subject with the statement that rectum constipation formed 60 per cent. of the 125 cases of which he has been making a special roentgen study. He emphasizes that it is important for treatment to know whether the colon or the rectum is the seat of the disturbance, and especially whether the ascending colon is involved or not.

129. **Influenza and Pulmonary Tuberculosis.**—Permin analyzes forty-five recent cases of influenza occurring in persons with pulmonary tuberculosis. All phases were represented and in some the tuberculosis was evidently aggravated but in quite a large proportion the intercurrent influenza has apparently harmlessly subsided. In eight other cases the first symptoms of tuberculosis developed after a recent attack of influenza. His practical conclusion is that the tuberculous must avoid infection with influenza with the strictest care, keeping away from contacts and poorly ventilated rooms, etc. There is reason to assume that the effect of the influenza will become more apparent in the course of the winter on persons with mild tuberculosis, and provision must be made for institutional care of an unusually large contingent of the tuberculous in the next few months.

130. **The Copenhagen Medical Society and the Epidemic.**—Bie records with great satisfaction the thorough organization of the Copenhagen Medical Society to handle the epidemic of influenza, with the aid of volunteer motor car drivers, visiting nurses and women to help them, and financial and other support from the city authorities. The school kitchens were utilized to prepare food for the sick, and volunteers distributed it. One of the newspapers collected a subscription which was given to the medical society, enabling the members to relieve pressing needs as they met them, and this without public charity. Enough of the money is left to organize some convalescent homes which will fill a great want. On the whole, the systematic organization of the medical society in this emergency has worked with surprising smoothness and efficiency both for physicians and the sick.

131. **Fatal Cocain Poisoning.**—The man of 52 died on the table after local anesthesia for a herniotomy, and it was found that a 10 per cent. solution of cocain had been injected by mistake instead of the supposed 2 per cent. novocain solution. The bottles were kept on the same shelf, with the same size, shape and color of label, and Møller protests against this practice, urging that dangerous substances should be kept in special vials. The sudden death had been inexplicable at first, the convulsions, clonic spasms, cyanosis and coma proving fatal notwithstanding stimulants, artificial respiration and massage of the heart. This communication is an abstract from a Swedish journal.

VOL. 72, NO. 3 CHICAGO, ILLINOIS JANUARY 18, 1919

A BACTERIOLOGIC STUDY OF THE INFLUENZA EPIDEMIC AT CAMP DEVENS, MASS.

LESLEY H. SPOONER, M.D. (BOSTON)
Major, M. C., U. S. Army
JOSEPH M. SCOTT
AND
ELMER H. HEATH, JR.
Second Lieutenants, S. C., U. S. Army
CAMP DEVENS, AYER, MASS.

Camp Devens had been somewhat forewarned of the impending epidemic of influenza through rumors of its existence in the naval district about Boston, so that on September 7 the admission from one company of fourteen men with ill-defined fever aroused immediate suspicion. These patients were at once isolated, and an intensive study was started on them. Blood and urine cultures were consistently negative; those from the nasopharynx were also unsatisfactory, owing to the fact that the technic employed at that time was in some respects inadequate. None of these first patients had deep enough pulmonary involvement to yield satisfactory sputum, so that it was impossible to utilize that method of diagnosis.

A detailed account of the epidemic is not within the scope of this paper. It is quite sufficient to state that the disease spread like wildfire, and that in the course of four or five days the hospital was filled with cases of the disease.

This report will deal with bacteriologic findings alone. A pathologic study has been in progress in this laboratory from the start of the epidemic. Dr. S. Burt Wolbach, to whom we are indebted for many of the postmortem cultures cited in this paper, is at present engaged in an intensive study of a limited number of necropsies, which will be reported by him at a later date.

From the beginning of the epidemic, routine "sputum typing" was as usual carried out in cases suspected of pneumonia. Freshly prepared smears of sputum and the peritoneal exudate of inoculated mice showed such a frequent occurrence of a small, gram-negative bacillus, that this organism was at once considered as a very likely etiologic factor of the disease.

This investigation includes a study of cultures from the lungs, accessory sinuses and heart's blood at necropsy; and those derived from the sputum, nasopharyngeal secretions, pleural exudates, and blood of patients acutely sick with the disease.

TECHNIC

The medium employed was 2 per cent. agar, 0.2 per cent. of normal acid, enriched with hemoglobin. This was at first secured by pouring human blood over the surface of agar plates, but it was soon found more satisfactory to use 10 per cent. defibrinated blood agar plates. By this method the colonies were found to be much more distinct, and isolation was greatly facilitated. The latter was also favored by drying the surface of the medium by the introduction of filter paper into the cover of the dish, before sterilization.

MORPHOLOGY

The gross morphology of the cultures and the microscopic appearance of the organism correspond exactly with that of the bacillus of influenza of Pfeiffer. The colonies are minute, spherical, elevated, colorless, translucent, discrete and moist. They appear along the line of inoculation, spreading only a short distance from it, and always remaining as discrete colonies. At the end of twenty-four hours they are scarcely visible and are often confused with the material that has been streaked on the surface of the medium. At the end of forty-eight hours the growth is generally well marked and is as described above. The organism is an obligate aerobe and on blood on agar plates appears only at the edge of the superimposed blood. This is another reason for adopting the blood agar plate described above.

Frequent transplantation is necessary in order to insure the viability of the culture. On an average, tubes left for one week at room temperature have been found sterile. Of thirty-eight cultures shipped by mail from this laboratory to the Army Medical School in Washington, only two failed to grow on reinoculation.

Artificial enrichment of mediums by the growth of *Staphylococcus aureus* was attempted according to Besson. The addition to the mediums of dead cultures of such organisms not only did not promote growth of *B. influenzae*, but apparently caused a retardation. When, however, *Staphylococcus aureus* was streaked across a plate already impregnated with *B. influenzae*, the latter showed a marked increase in growth in the immediate vicinity of *S. aureus* streaks, large colonies being evident in from eighteen to twenty hours.

Similar results were obtained by the symbiotic action of *B. subtilis*, effected by connecting the two culture tubes, separately impregnated, by a short rubber tubing.

Microscopic Morphology.—The organism is a minute, gram-negative bacillus, varying in length from coccoid to filamentous forms. The older cultures show a marked pleomorphism. The organism decolorizes with gram stain. Polarity is evident especially with methylene blue and dilute carbolfuchsin.

PATHOGENICITY

More than a hundred intraperitoneal injections of mice have shown that the organism is not pathogenic to that animal.

Two sets of experiments have failed to reveal evidence of pathogenicity of this organism to guinea-pigs, either from intraperitoneal or from intravenous injection. For all injections the following technic was employed: *B. influenzae* was grown on blood agar slants in 75 by 10 mm. tubes for forty-eight hours. To each slant was added 1 c.c. of sterile saline solution and a uniform mechanical suspension obtained.

The rabbit was considered as the best animal for the production of antiserums, and for this purpose three methods were employed, all being controlled by two animals, and by parallel animals not inoculated. One set of animals received intraperitoneal injections, one intravenous, and the last intratracheal insufflations. All animals were isolated, except as noted, and carefully watched. Temperatures were taken twice daily. In every instance there was an initial rise of temperature much more prompt in its appearance in the intravenous and insufflation experiments than in the intraperitoneal. This temperature, which ranged between 104 and 106 F., persisted for from twelve to thirty-six hours, generally falling to normal gradually. (The normal has been considered to be between 101.5 and 103.5 F.)

Necropsy has failed to show evidence that any disease process, similar to that produced by B. *influenzae*, resulted from these experiments.

Only two of the animals have been sick. Rabbit 7—or Insufflation 1—developed a coryza twelve hours after the introduction into the trachea by direct operation of 0.5 c.c. of suspension of pure culture of *B. influenzae*. The purulent secretion from the nose showed a pure growth of *B. influenzae*.

A healthy rabbit was placed in the same cage with this infected animal for four days, but has remained healthy up to the present time.

Rabbit 7 was etherized, bled, and killed five days after insufflation. The trachea showed extensive injection of the mucous membrane, which was covered as far as the bifurcation with dirty mucosanguineous secretion. Smears and cultures from this area were negative. The lungs showed no evidence of pathologic involvement. The parallel insufflation experiment on Rabbit 8 was negative except for the immediate reaction, described above, following two insufflations, the latter of 2 c.c. of suspended culture. Rabbit 5, two days following the third intraperitoneal injection (of 1.5 c.c. culture), developed a temperature of from 106 to 106.2 F. and rapid and labored breathing. These symptoms persisted for two days. At that time the animal was etherized and bled for serologic purposes. This rabbit died three days following this operation. Necropsy revealed no gross pathologic condition except an extensive hemopericardium, the result of repeated heart punctures. The tissues are now being prepared for microscopic examination; but it seems very remote to expect any pathologic change as a result of inoculation. From these experiments it is evident that no typical pathologic lesions have been produced in the rabbit by injections of *B. influenzae*.

BACTERIOLOGIC FINDINGS

In the work about to be described, the presence of *B. influenzae* in the smear alone has always been thought inconclusive. It has always been considered necessary to isolate the organism in pure culture to warrant a report of positive findings. The influenza bacillus has been isolated from the sputum in 104 cases. It was first recovered from blood agar subcultures of the peritoneal exudate and heart's blood of mice inoculated with sputum according to the method advised by Blake[1] for the typing of pneumococci. It was found, however, that it was not necessary to resort to this device to secure a culture, unless it was desired to ascertain the presence of a mixed pneumococcus infection, for the careful inoculation of a blood agar plate with washed fresh sputum yielded positive results in a surprising number of attempts.

It was felt from the very beginning of this work that, although *B. influenzae* was so frequently present in this epidemic, mixed infection played a very important rôle in the progress of the complicating pneumonias. For this reason the routine sputum typing was continued and the results are of considerable interest (Table 1). Too much weight should not, of course, be placed on the occurrence of a mixed infection with Type IV pneumococcus; that with Types I, II and III and with *Streptococcus hemolyticus* is of great interest. The therapeutic importance of such an infection has been considered in a previous report by one of us (L. H. S.[2]).

Total B. influenzae cultures from sputum	104

Nasopharyngeal swabs were made in a few fresh cases shortly after the epidemic had reached its height. They were positive in seven out of ten trials. In the later stages they were positive in four out of eight cases—a total of eleven positive cultures.[3]

PLEURAL FLUID CULTURES

Similar results have been found on cultivating pleural fluids in cases of empyema complicating the pneumonias of this epidemic. They are presented in Table 2, from which it will be seen that eight times the influenza bacillus has been isolated from chest fluids: twice alone and six times in conjunction with other organisms.

[3] For this technic and for suggestions in cultural methods we are indebted to Capt. Oswald T. Avery, M. C., U. S. Army.

BLOOD CULTURES

The blood of pneumonia patients has been cultivated during the past month as systematically as possible; 118 cultures were taken, with twenty-eight, or 24 per cent., positive cultures, and ninety, or 76 per cent., negative cultures. The pneumococcus was found in twenty-seven, and *Streptococcus hemolyticus* in one. The character of the organisms isolated is presented in Table 3, which covers the height of the epidemic and from which it will be seen that in no instance could *B. influenzae* be recovered from the blood, but that a slightly higher percentage of positive pneumococcus cultures was obtained than was found previously in this laboratory.

POSTMORTEM CULTURES

During the early days of the epidemic it was often impossible to devote as much attention to a careful study of the bacteriology of necropsies as would have been desired under other circumstances. Many of the necropsies were performed so many hours postmortem that such cultures were not taken, because it was felt that they would have been worthless. Also during the busier times it was impossible to type the pneumococci isolated from the blood and other sources.

For this reason it is possible to report only thirty-seven cases which have been studied thoroughly enough to warrant their admission as reliable evidence. In all cases the organisms have been recovered in pure culture and their identity proved by cultural characteristics and microscopic morphology and staining reaction.

234	Pneumococcus II	B. influenzae, Pneumococcus II, Streptococcus viridans

Table 4 shows the result of heart's blood and lung cultures; the former taken by a pipet into nutrient broth, the latter from the seared lung on the surface of blood agar plates.

The great significance of *B. influenzae* as an etiologic factor of the pneumonia in this epidemic may not be clearly brought out by Table 4, which shows the preponderance of organisms found in all lobes of the lungs at each necropsy. It is very significant, however, that *B. influenzae* was found in pure culture in at least one lobe in sixteen of thirty-seven necropsies. The necessity of early necropsy is shown by the fact that successful attempts to isolate the organism resulted twenty times when examination was made less than five hours postmortem, and in only three when a greater time had elapsed.

It will be seen that *B. influenzae* has been recovered from the lung in twenty-three necropsies. The occurrence is given in Table 5.

Total	37

B. influenzae occurred alone or with other organisms in twenty-three, or 62 per cent., of thirty-seven cases.

In addition, *B. influenzae* has been recovered from the frontal sinus in four cases; from the sphenoidal sinus in eight, and from the middle ears in two. These occurred in the manner shown in Table 6.

(Two cultures showed two organisms.)

It is well recognized that *B. influenzae* is difficult to isolate from the heart's blood; but the high percentage (65 per cent.) of pneumococci found at this time shows the importance of mixed infection.

It is the object of these figures to show that, although *B. influenzae* is present in frequency enough to warrant the statement that it was the most important etiologic factor of this epidemic, yet considerable importance must be placed on the secondary invaders, the pneumococcus and in this hospital rarely the *Streptococcus hemolyticus*, which are found in such a large percentage of cases examined, both during life and postmortem.

SEROLOGIC INVESTIGATION

Macroscopic agglutinations have been performed on various individuals, at first with homogeneous serum and later with heterologous serum. The technic employed was as follows: A uniform moderately turbid suspension of *B. influenzae* was obtained from washing the surfaces of forty-eight hour blood agar slant cultures. Dilutions were made ranging from 1 : 2 to 1 : 800 in agglutinating tubes, which were incubated in the water bath at 37 C. for from twelve to eighteen hours. It was found that readings were facilitated by placing the tubes after incubation in the ice box for from four to six hours. Saline controls were run at the same time. A distinct but fine flocculent precipitate was read as +; heavier and coarser precipitate as ++, and large masses of agglutinated organisms as +++. Tables 8 and 9 are illustrative of the fact that the formation of agglutinins takes place gradually after the disease and that there is no strong evidence to favor a variety of strains of *B. influenzae,* since no difference in titer of the most potent serums was found with either homogeneous or heterologous cultures. It is interesting to note the frequency of negative readings in low dilutions in serums that show a high titer. A series of controls, taken from members of the staff of this laboratory, showed no natural agglutinin for this organism.

* Homogeneous culture † Heterologous culture.

Even more striking results are shown in the agglutinin reactions in rabbits at varying stages of their "immunization" with living cultures. In the later titrations the lower dilutions have been omitted.

Very unsatisfactory results have come from a few efforts to demonstrate specific precipitins and bacteriolytic substances, although the results are encouraging enough to warrant further study.

COMMENTARY

It is perfectly obvious that it is impossible to prove the etiologic factor of a disease when, with the best available technic, the organism in question is not, strictly speaking, "constantly present" in the lesions, and when it is impossible to reproduce the disease in lower animals by inoculation.

It seems reasonable to suppose that the prime factor in this epidemic was *B. influenzae,* since it was found in such a large proportion of specimens of sputum when the latter was derived from the lower air passages and was properly examined; since the organism was recovered from lungs postmortem in 62 per cent. of those cases carefully studied, and in pure culture from at least one lobe in 50 per cent. of the same series; and since the blood of patients convalescent from the disease showed a rising agglutinating power not only to their own organism, but also to heterologous cultures.

The following points must be borne in mind in any study of this organism: The demonstration of organisms morphologically similar to *B. influenzae* in smears is insufficient for diagnosis, but such organisms must be cultivated in pure culture on hemoglobin mediums, and subsequent transplants on hemoglobin-free mediums must show no growth.

Although the organism grows better in symbiosis with other organisms, especially the staphylococcus, there is great danger of overgrowth.

Care should be taken not to discard cultures as negative, since in many instances appreciable growth does not appear until after from forty-eight to seventy-two hours' incubation.

The direct smear method is of value in indicating what may be expected in culture. The most striking fact in regard to such preparations lies in the great frequency of intracellular *B. influenzae.*

Too great stress cannot be laid on the absolute necessity of immediate necropsies if one is anxious to recover this organism, before overgrowth renders such results impossible.

CONCLUSIONS

1. *B. influenzae* has been isolated from pneumonia sputum, pleural fluids, and the nasopharynx during life, and from the heart's blood, lungs, and accessory sinuses postmortem in a high percentage of cases of this disease, very frequently in pure culture.
2. Specific agglutinins have been found in the serum of convalescents which produce satisfactory reactions, especially during the weeks following infection, on homogeneous and heterologous cultures.
3. A high titer serum has been produced in rabbits by repeated inoculations with living cultures. This serum has shown an increase of potency with the passage of time. Such serum should be of value as a means of differentiating allied organisms.

EDEMA OF THE BRAIN IN THE INFECTIOUS DISEASES

C. T. SHARPE, M.D.
NEW YORK

Little is to be found in the literature relative to edema of the brain in the infectious diseases as a clinical entity, and much less, therefore, if anything, as to edema as a clinical type of an infectious disease. We are all familiar with the occurrence of meningismus in acute diseases, and during the febrile stage are not surprised to have some evidence of it; but how many of us are prepared to take the position that edema does, in some cases, develop to such an extent that it masks the ordinary clinical picture of the disease and may occasion doubt as to the diagnosis?

Edema of the brain may and does appear at different periods in the course of the infectious diseases. When it occurs early it may hide the true nature of the illness and it has been noticed on several occasions that with the predominance of this feature there may be an atypical rash and the picture so unusual that grave doubt arises as to the basic diseases. When it appears late the difficulty is increased greatly, because if we are unaware that such is to be expected and looked for we may be somewhat disconcerted and wander from Dan to Beersheba, seeking the correct diagnosis, and return empty handed.

The recent epidemic of poliomyelitis offered unusual advantages for the clinical study of edema of the brain. The mental attitude of the patients is one of the most striking features, and all variations from hyperexcitability to melancholia, from gibberish to silence, associated with and without paralysis, but always with edema, were noted. In our study of these cases we soon appreciated the difficulty of reaching any agreement as to the interpretation of the Macewen sign on the basis of sound and we adopted a modification of the sign, as described, and based our findings on the difference in resistance noted on percussion. Increased resistance on percussion was used as a guide to treatment and was the determining factor in the performance of lumbar puncture. It was interesting to observe how readily visitors to our wards took up this method and how regularly an agreement as to findings was reached.

It will, no doubt, be admitted readily that a clinical diagnosis of edema of the brain may be correctly made from a study of objective symptoms alone, and more readily admitted that in poliomyelitis it is one of the most frequent symptoms. It will not be so readily admitted that in the infectious diseases the same condition is to be found; nevertheless, it is possible to establish by the same signs and symptoms the same clinical facts and to confirm these in various ways. As in poliomyelitis, so in scarlet fever, measles and diphtheria the edema of the brain exists; as in poliomyelitis, so in the diseases mentioned the amount of the edema changes the clinical picture from the generally accepted type to one that may lack characteristic symptoms. In scarlet fever the rash may be atypical and the mental condition marked, and grave doubt may arise unless we recognize the variation in type. As in poliomyelitis, so in the diseases mentioned this edema may persist for weeks after convalescence is established.

TIME OF OCCURRENCE

From the very beginning, the mental symptoms may predominate; or they may not develop for from twenty-four to forty-eight hours or longer after the onset. They may not develop until the third week, and again, they may not be sufficiently evident until after convalescence is well established—after the fourth week in scarlet fever and after the second week in measles—to give rise to any serious thought. In hospital practice it is not unusual to have a child sent in who has been ill for from six to eight days, who shows no evidence of scarlet fever or other infectious disease, who is delirious and who may prove very hard to control. Here the history may help and the case is isolated; but if a patient is admitted and there is no such history to guide one, a grave injustice may be done other patients. It is well, therefore, to consider the possibility of the infectious diseases if such a case presents itself in private or hospital practice.

ANALOGY TO SYPHILIS

It would seem that there is some analogy between syphilis and the infectious diseases. It is well known that a syphilitic patient presenting marked cutaneous symptoms may be absolutely free from any involvement of the nervous system, and may never develop a nerve lesion. Again, patients present themselves showing all grades of involvement of the nervous system who cannot recall ever having had an eruption of the skin. One may hesitate to believe that these patients never showed any skin manifestations, but one must admit that the rash must have been very insignificant to have escaped recognition or, in other words, that the rash was atypical.

INTERRELATIONSHIP BETWEEN CUTANEOUS AND SPINAL PRESSURE

In presenting the history of an interesting case of cerebrospinal meningitis to the Pediatric Section of the New York Academy of Medicine a year ago, I made this observation:

> It would seem that when the spinal symptoms are marked, the cutaneous symptoms may be negative and vice versa. That this interrelationship holds I have long been convinced.

same picture as noted in the cerebrum. The choroid plexus was chiefly interesting because of the presence of numerous psammoma bodies.

CONCLUSIONS

1. Edema of the brain occurs in the infectious diseases.
2. Its presence not infrequently masks the symptoms of the disease in which it is due, and it may be considered as a type per se.
3. The primary involvement may be that of the central nervous system.
4. There is an interrelationship between the cerebrospinal pressure and that of the cutaneous circulation. This relationship is one of direct variation.
5. The outbreak of a marked cutaneous eruption in a case presenting symptoms of intracranial pressure is a favorable prognostic omen. These patients recover.
6. Lumbar puncture is indicated in these cases.
7. White light electric baths, in that they favor an increased cutaneous circulation, are beneficial and are preferable to hot tubs of from 105 to 110 F., though the latter are productive of good results.

25 West Forty-Fifth Street.

CARDIOVASCULAR EXAMINATIONS OF FIFTY-FIVE THOUSAND RECRUITS

GEORGE EDMESTON FAHR, M.D.
Contract Surgeon, U. S. Army

Assisted by Lieuts. D. W. Carter, M.D. (Georgetown, Texas); J. H. Cosgrove, M.D. (Duluth, Minn.)
and J. D. Edgar, M.D. (Henry, S. D.)

CAMP TRAVIS, FORT SAM HOUSTON, TEXAS

There is no reason why diseases of the heart should not be given equal rank with tuberculosis, for in civil life they result in at least as many, if not more, deaths. In the Allied armies more disability is due to cardiovascular disease than to tuberculosis. The recent report to Parliament showed that of the 350,000 men in the British army discharged and pensioned for wounds and diseases, a little over 10 per cent. were for heart disease and about 11 per cent. for chest complaints and tuberculosis. When we consider that whenever tuberculosis is found in the soldier he is discharged and pensioned, whereas very many of the men with cardiovascular disease are not discharged but are merely put in deferred classes of the Army, we see that circulatory diseases are undoubtedly of more importance to the Army than tuberculosis. It will surprise many to know that there are two and one-half times as many pensions for heart disease in the British army as there are for the loss of limbs, and nearly twice as many as for nervous diseases, shell shock and epilepsy together.

The cardiovascular board examining recruits at Camp Travis, Texas, has completed the examination
of 55, [illegible] ls itself in possession of informa-
[illegible] the standpoint [illegible] tatistics as well
[illegible] ir efforts to
[illegible] camps who
[illegible] ion because

[illegible] at Camp Travis
[illegible] ving at the
[illegible] e receiv-
[illegible] from the
personnel board, are stripped, given a shower bath, and then sent to the various special boards examining in the same group of buildings. The last board to examine them is the cardiovascular board. This board has its quarters in the quietest wing of the building. The two members of the cardiovascular board working in this building simply attempt to pick up cases for more thorough examination. It is thus possible for two examiners to complete the examination of 1,500 men for cardiovascular disease in one day. An attempt is made to differentiate murmurs due to valvular lesions from purely accidental ones and to select as far as possible only such cases of tachycardia for more thorough examination as show the other symptoms of irritable heart or hyperthyroidism. A much more extensive examination is then given the selected cases by the third member of the board, who has his quarters in an adjacent building with the discharge board of the camp. After this examination, the recruit is classified and accepted or discharged.

The two members performing the first examination usually consult over each case before sending it to the discharge board, and the member of the cardiovascular board working with the discharge board consults and discusses the difficult and ambiguous cases with the other two members constantly so that no man is discharged from this camp without a thorough examination and critical discussion, unless the case is a very simple one. The cardiovascular board has also learned much from examination of a large number of enlisted men of the Ninetieth Division now stationed abroad. The board also receives a certain number of men from the training battalions into which the men had been inducted after the first cardiovascular examination, for reexamination and reclassification, who have been found unable to stand up at drill, showing signs of dyspnea, precordial pains or fainting on exertion.

We believe that our figures show approximately the amount of valvular heart disease incident to young men in the ages from 21 to 31 living in the states of Texas and Oklahoma. We can hardly believe that the majority of the local boards sending men to Camp Travis are capable of picking up many cases of valvular diseases of the heart. In the earlier draft increments, we found twelve men in 10,000 troops with aortic insufficiency, presenting symptoms of a large heart pulsating strongly in the axillary line with loud diastolic murmurs at the sternum and often at the apex, with typical Corrigan pulse and all the features of outspoken aortic disease, marked by local boards "heart normal." The last two increments yielded a smaller percentage. The last increment of 19,000 men yielded only eighteen cases. We have found the same to be true of mitral diseases. Local boards which could not discover the majority of the cases of aortic and mitral insufficiency discharged by us would certainly reject extraordinarily few of the cases of organic heart disease passing through their hands. Undoubtedly, however, the excellence of the work done by the local boards varies from board to board, so that our statistics do not give the actual percentage of young men suffering from these diseases; but they certainly give the order of magnitude of the incidence of valvular disease at these ages in these states.

AORTIC INSUFFICIENCY

We found fifty cases of aortic insufficiency in examining 55,000 recruits, that is, 0.09 per cent. With only a few exceptions, these were outspoken cases with loud diastolic murmur heard all over the sternum and often at the apex, with hypertrophy to the left, with Corrigan pulse, with high pulse pressure and all the other classic signs. In a few cases the murmur was very soft and faint and the hypertrophy slight. One of these men was a university athlete, a high and broad jumper. He was at the time of the examination able to undergo severe bodily exertion, but he had all the signs of aortic insufficiency and a history of polyarthritis in childhood. One of the most interesting cases was that of a Texas cowboy, a man who had been a "broncho buster." This man had once noticed while riding a wild horse that something seemed to break behind his chest bone and that there was pain present behind the sternum for some time. There was a high pitched musical diastolic murmur heard over the second intercostal space to the right and left and over the sternum. The pulse pressure was only a little larger than normal, there was no hypertrophy, and there were no signs of dyspnea on hopping. The man professed to be able to do hard work, but had found it necessary to give up broncho busting. It would appear that we might have here one of those rare cases of a rip in one of the semilunar leaflets brought about by a strain and trauma. Of course it is impossible to verify this without the records of examinations previous to the occasion when the accident supposedly took place. It is interesting to note that only once did a local board mark a case of aortic insufficiency anything but normal. In this one case in which the aortic diastolic sound was especially loud, was heard at the apex as well and was accompanied by an apex beat in the axillary line and by relative mitral insufficiency, the local board marked its findings "apex sound prolonged."

Most of the cases of aortic insufficiency were undoubtedly due to polyarthritis. In many of the cases there was also a history of syphilis; but the syphilis had been acquired only a few years before. In these young men with a history of polyarthritis, tonsillitis and syphilis it seems most probable that the lesion is rheumatic in etiology. The incidence of aortic disease in the colored race was slightly greater than in the white. Most of these afflicted with this lesion were doing hard labor. Some of them certainly appeared capable of the severe bodily exertion demanded of soldiers. In fact, they were often physically better than those whom we discharged for irritable hearts and in whom there was no valvular lesion. As long as the leakage is only slight and the heart muscle is capable of doing the extra amount of work necessitated by the leakage, these hearts respond very well to a call for severe exertion. It is later, when the increasing leakage puts an increasing handicap on the heart muscle and when the heart muscle begins to weaken, that these men notice symptoms. Pain over the sternum is often for a long time the only complaint. In this connection, we recall some cases of aortic regurgitation seen at Nauheim during the early period of the war. The men had served their period of enlistment years before, had developed an aortic regurgitation in the interim and were mobilized after a very superficial examination at the beginning of the war. These men were farmers and laborers and went through many days of hard marching with 75 pounds on their backs. At a time when men with healthy hearts began to be exhausted from the forced marches through Belgium and Russia, these men began to show signs of heart failure; pain, dyspnea, swollen ankles and hemoptysis. When once this exhaustion of their cardiac muscle had taken place, it seemed to be accompanied by a permanent impairment of the cardiac reserve, so that these men who had been mobilized as efficient laborers had to be discharged after treatment at the spa as partial invalids capable of only light work. For this reason, we are convinced that it is best to exclude all men with aortic lesions, even when the leakage appears slight and the heart muscle capable of taking care of it.

MITRAL INSUFFICIENCY

There were thirty-nine cases of mitral insufficiency unaccompanied by another lesion, that is, 0.07 per cent. It will probably astonish many who believe that mitral insufficiency is relatively a very common valvular lesion. On the other hand, we believe that those who have had considerable experience with heart disease, both clinically and pathologically, will agree that mitral insufficiency of endocarditic origin and uncomplicated by mitral stenosis is relatively not very much commoner than aortic insufficiency. Relative mitral insufficiency accompanying myocarditis in the middle aged and old, or associated with other valvular lesions, is relatively, of course, very common. There has been a tendency to consider a loud systolic murmur at the apex pathognomonic of mitral insufficiency. Many of these murmurs are undoubtedly not due to valvular lesions at the mitral orifice. It is true that the members of the local boards will undoubtedly pick up and discharge more cases of mitral insufficiency than aortic insufficiency because the mitral systolic murmur is much more easily recognized than the softer aortic diastolic murmur. On the other hand, we cannot believe that the local boards have picked up and discharged very many cases of simple endocarditic mitral insufficiency, for these boards have sent to camp a large number of men with loud systolic murmurs which on careful examinations have turned out to be accidental murmurs, but which had not been noted by the local board.

ACCIDENTAL MURMURS

Our experience in reviewing the findings of physical examinations at one of the largest universities in the country and as members of medical advisory boards, as well as here at Camp Travis, have shown us that the average practitioner has not had the great incidence of accidental heart murmurs in the young impressed on him sufficiently. We have never forgotten the case of one of our college classmates who was advised against taking part in athletics because he had a "leakage of the heart." This man became famous as a cross-country runner and as 2-mile champion both here and abroad to the astonishment of the examining physician, who had heard a systolic murmur. We have seen numbers of young men turned down by the examiners for the Aviation Corps and the Navy for nothing more than systolic accidental murmurs, some of them heard in the second interspace. Some of the men appearing before us for examination present statements from one or more physicians vouching for their inability to become soldiers because of valvular lesions. All these men show nothing but simple accidental murmurs. Every cardiac consultant can recall many young lives at least temporarily blighted by one of these diagnoses. One of the men examined by us had been turned down by the local board with the stat

"Physically deficient by reason of cardiac murmur." The advisory board had diagnosed it "mitral regurgitation," but for some reason had passed the man. The murmur was an accidental one heard best in the third left interspace. The etiology of mitral regurgitation in this case will certainly be of interest to the readers of this article. The young man had been in love with a girl. He had bought himself a homestead, had worked hard on this, doing his own house work as well as field work and hoped finally to lead the blushing bride back to the farm which he was preparing for her. When all was ready, the girl turned him down. According to his statement, this caused him heart trouble. On close questioning his trouble seemed to be more in his stomach than in his heart, and we felt that despite this very real "heart" trouble he might still make a good soldier.

We found that 3.2 per cent. of all our recruits have an accidental murmur; and by accidental murmurs we do not mean reduplicated and impure first sounds but real murmurs with a swish or rumble, often very rough and loud, and in quality indistinguishable from the murmurs associated with real organic lesions. As Lewis has insisted, in the examination of English soldiers, "neither the quality, intensity nor transmission of a murmur is sufficient for distinguishing it." There is a soft systolic murmur usually disappearing on recumbency which most physicians distinguish as an accidental murmur, but many of the loud, rough systolic murmurs transmitted into the axilla lead to the diagnosis, "mitral insufficiency." In one of the latest American works on the physical diagnosis of the chest we find the false statement that "accidental murmurs are never loud and rough." It must be insisted on that whenever there is an organic insufficiency at the mitral valve of any importance, the left ventricle must dilate in order that the heart may do the extra amount of work set for it and pump out the increased minute volume. The regurgitation of blood backward must lead to increased pressure in the pulmonic circulation with accentuation of the pulmonic second sound and dilatation of the left auricle. Without hypertrophy and signs of embarrassment of the pulmonic circulation, there should be no diagnosis of mitral insufficiency excepting, of course, when the physician has heard a systolic murmur developed during or following rheumatic fever or other infections. Even then the diagnosis must be made with reserve unless the other signs are present. We recall here the case of a recruit recently examined by us. He had been rejected for the Texas cavalry because of an extremely loud and rough systolic murmur. This boy had two typical attacks of polyarthritis in childhood. When we examined him, the pulse rate was 108; but the young man told us he had many times examined it himself and had always found it to be 70. The apex beat was well within the midclavicular line. Percussion of the left border showed it also inside the midclavicular line. The pulmonic second was louder than the aortic but not accentuated; the response to effort was good; he played baseball and was a good swimmer. We were all agreed that despite the history of polyarthritis in this case, there was practically no regurgitation through the mitral valve. We do not care to discuss here what may be the causes of these murmurs; but we do wish to point out that the loudest systolic murmur unaccompanied by definite signs of pathologic anatomy and of pathologic physiology in the circulation should not lead to a diagnosis of valvular lesions. The left auricle in contradistinction to the left ventricle cannot be burdened with even moderate amounts of regurgitated blood without embarrassment to the pulmonary circulation.

Good judgment must also be exercised in making use of a pulmonic second sound louder than the aortic. The pulmonic second is usually louder than the aortic in men at these ages, especially when recumbent. If the pulmonic is not merely louder but is accentuated or reduplicated, this evidence is in favor of the diagnosis of mitral disease. But we have found cases with reduplicated and accentuated second pulmonic sounds in hearts without murmurs or hypertrophy and with no symptoms.

The determination of hypertrophy of the left ventricle is fraught with uncertainty in many cases if percussion and position of the apex beat are the only means for determining the left border of the heart. It should be emphasized that the apex beat is not always a reliable index of the position of the left border. Usually the apex beat is inside the left border of the heart as determined by the orthodiagram or accurate percussion; but sometimes the apex beat is one or more centimeters outside the left border as determined by the orthodiagram, especially when the heart is overactive. Hypertrophy of the left ventricle was once diagnosed in the author by a very good clinician because the apex beat was strongly felt in the anterior axillary line. An orthodiagram of the heart showed the left border to be well within the normal limits. This led to the investigation of a number of thousands of cases by Professor Weber at Nauheim. It was found that many patients with supposed dilatation determined by the position of the apex beat and sent to this spa for treatment showed normal orthodiagraphically determined borders, the real apex being seen on the fluoroscopic screen of the orthodiagram to be pulsating well inside the nipple line. In the course of our examinations of 55,000 men we have found the apex beat in many cases outside the nipple line in hearts whose border as determined by roentgenoscopy or percussion was inside the nipple line. This was found to be especially the case in those chests in which the thorax suddenly curved posteriorly before the nipple line was reached. In these chests the thrust of the apex is propagated out beyond the actual position of the apex in the frontal plane. We believe that careful percussion conducted in a very quiet room by physicians who have practiced and carefully controlled their percussion orthodiagraphically in hundreds of cases is often superior to the palpation of the apex beat in determining whether a hypertrophy is present or not. Of course, whenever possible, roentgenographic methods, making use of parallel rays, are the methods of choice.

The response of the heart to effort may aid in determining whether the possessor of a systolic murmur has an organic heart lesion or not. But this may also leave us in doubt, for many cases of irritable heart that have a poor response to effort also show a systolic murmur. Critical judgment and an extensive experience in the physical signs of normal and pathologic hearts is indispensable in finally deciding where to place certain cases; but usually we have not found it difficult to determine when a systolic murmur is the sign of a real organic lesion at the mitral valve. We desire again to emphasize the great value which percussion of the heart borders, combined with a comparison of the orthodiagram of the heart, has been to us personally in determining the accuracy of our percussion. We have had success in the teaching of percussion to students by this method. If this method were followed in all our medical schools, we feel that there would be fewer diagnoses of left ventricular hypertrophy, on hearing murmurs that are undoubtedly accidental.

The greater part of the accidental murmurs (2.5 per cent.) were systolic and loudest over the apex. About 0.6 per cent. of all the recruits showed systolic murmurs loudest over the second left intercostal space. Only about 0.2 per cent. showed pronounced cardiorespiratory murmurs. About 0.2 per cent. showed murmurs loudest over the second right interspace and transmitted into the carotids. There were none of the other symptoms of aortic stenosis, and neither roentgenoscopy nor percussion showed any enlargement of the arch. There were no symptoms, and therefore both aortic stenosis and aortitis being reasonably surely excluded, the diagnosis of accidental murmur was made. There were four recruits (less than 0.01 per cent.) found with diastolic murmurs after due deliberation classed accidental. These murmurs are very soft and usually heard only in the earlier parts of diastole. They are usually influenced by respiration, nearly disappearing on inspiration. There is no history, and there are no symptoms nor any signs of aortic insufficiency associated with these murmurs. In one case there was a peculiar diastolic murmur heard over the second right interspace over the whole of the lower sternum and to the right of it when the recruit was standing. This murmur was increased on expiration but did not disappear on inspiration. In the recumbent position, there was no diastolic murmur heard, its place having been taken by a soft systolic respiratory murmur. The blood pressure was 130 and 80; tonsillitis was the only disease in the patient's history. There was no hypertrophy, and the recruit had never experienced dyspnea or pain over the chest; in fact, he remarked that he always feels well. Here again, we see that no one symptom alone is pathognomonic. Time and again we have had cases in which there was no pathologic condition referred to us with a diagnosis made from one symptom alone.

STENOSIS, HYPERTROPHY AND OTHER CONDITIONS

Mitral stenosis is apparently very rare in the states of Texas and Oklahoma. We have found only ten cases of undoubted mitral stenosis (presystolic murmur, accentuated second pulmonic, typical mitral outline) in an examination of 55,000 men. Rheumatic fever is probably very uncommon in these states. We have been very careful not to diagnose a mitral stenosis unless there was a definite typical presystolic murmur with accentuation of the second pulmonic sound.

We are altogether opposed to making a diagnosis of mitral stenosis from a loud, slapping first sound. If there is no presystolic murmur or thrill, there is no stenosis in these early stages. We have never been able to confirm Mackenzie's statement that the presystolic thrill is to be felt before the murmur is developed. At least by the man of slight cardiovascular experience, the presystolic thrill alone should never be used to diagnose a case. There are certain impurities of the first sound suggestive of presystolic murmurs that have led to the diagnosis of mitral stenosis. Some years ago we showed by graphic records that there are a few sound vibrations in the first 0.1 second preceding the normal first sound.[1] In some individuals, these vibrations have considerable amplitude. In one man investigated by us graphically, these vibrations varied in amplitude, on some days being loud enough to cause an impurity of the first sound. But these impurities are never as loud nor as prolonged nor of cresendo character, and so far as our experience goes never accompanied by the loud, slapping first sound of mitral stenosis. Exercise usually causes them to disappear, whereas the true presystolic murmur of mitral stenosis is increased in duration and intensity after exercise. The impurities should not cause the cardiovascular examiner any trouble if he is careful to consider all factors. The presystolic sound of mitral stenosis is not easy to recognize, and it is very probable that only such cases as were badly decompensated were recognized by the local boards. We believe that our figure for the incidence of mitral stenosis gives a tolerably fair idea of the order of frequency of this disease in Texas and Oklahoma.

We have found aortic stenosis complicating very few of our cases of aortic insufficiency. We have found no case of uncomplicated aortic stenosis. There have been many cases with a systolic murmur on the second right interspace and transmitted into the carotids, but unaccompanied by thrill over the interspace, by the typical pulsus durus and the faint second aortic sound. These cases have always been classified as accidental murmurs.

There were six cases of idiopathic hypertrophy with no apparent cause. There was no hypertension at the time of the examination, and it was not possible to observe these cases over a long period. Very possibly the hypertrophy was associated with periodic crises of hypertension. Ten recruits had hypertension, that is, a systolic pressure continuously above 160 mm. There were symptoms of nephritis in only one. One case suggested Pal's vasomotor crises. This man gave a history of attacks with severe pain over the chest, throbbing in the head, flushing of the face and headaches. His blood pressure was very labile during the period that we had him under observation, the systolic pressure ranging from 170 to 220.

Among the rare heart diseases we found one case of heart block with a rate of 38 and Stokes-Adams syndrome. There was no increase in the rate on exercise or after atropin. There was a history of syphilitic infection two years before. The fainting spells began five years before so that syphilis probably has no connection with this case of heart block. We also found one case of patent ductus arteriosus with a typical to and fro murmur in the second and third left interspaces transmitted to the interscapular region on the left side, with a loud second pulmonic sound, and pulsation in the third left interspaces. There was no hypertrophy, and the man felt perfectly capable of every exertion. He was accepted for service. There was one case of congenital septum defect, marked cyanosis since birth, clubbed fingers, moderate dyspnea on slight exertion, a loud systolic murmur heard best over the lower end of the sternum and to the left of sternum in the fourth interspace. This murmur was transmitted to all parts of the anterior chest wall and also into the back. The second pulmonic sound was loud. There was no enlargement to the right. We believe that the best guess in this case is patent *foramen ovale*. There was one case of dextrocardia with situs inversus. There were only seven cases of hyperthyroidism.

---

[1] Fahr, G. E.: On Simultaneous Records of Heart Sounds and Electrocardiogram, Heart 4: 147, 1912.

Excepting for the respiratory arrhythmia, common at this age, irregularities in rhythm are fairly rare. We have found that about 0.05 per cent. of all have extrasystoles of ventricular origin with no other pathologic condition. Sometimes they were associated with bigeminal pulse, and sometimes with no pulse following the second systole of a coupled beat heard at the apex. Usually these men were conscious of a compensatory pause, stating that their heart missed beats. It is customary for these extrasystoles to disappear entirely in a day or two after the excitement of mustering is all over. In the examination of 55,000 men, we have found but one case of pulsus irregularis perpetuus, a case of mitral stenosis and insufficiency with a soft diastolic murmur at the apex.

NEUROCIRCULATORY ASTHENIA

The condition previously known as irritable heart, but recently better designated as neurocirculatory asthenia, is by far the most important circulatory disturbance, both to the medical officer culling out at the recruiting station and to the medical officer examining at the front. For example, the report of one of the British base hospitals in France shows that out of 5,000 soldiers examined for circulatory failure only 5.5 per cent. had organic lesions and about 86 per cent. showed the condition known as irritable heart. In fact, the diagnosis of irritable heart is so much more important to the military surgeon than the diagnosis of organic lesions that Lewis makes the somewhat radical statement that the military heart specialist has no use for a stethoscope. Our experience at this camp seems to show that about 0.4 to 0.5 per cent. of all the recruits should be discharged for inability to stand up under severe bodily exertion because of neurocirculatory asthenia.

A brief description of the symptomatology of neurocirculatory asthenia[2] is perhaps not out of place at this point, especially as the condition has heretofore been described as seen at the front and not as observed in the training camp. Neurocirculatory asthenia, or the irritable heart of the soldier, as it is often designated, is not a condition determined by the exertions and emotional upsets of military life alone. This condition always exists among civilians. Careful inquiries have shown that among a large number of those who break down at the front with this disease, the symptoms were already present in civil life. The severe bodily exertion and the emotional stimuli associated with modern wars serve to bring out and emphasize this condition. Moreover, it is peculiarly inherent in the modern methods of conducting warfare. When military service is confined to a class who practice it voluntarily, irritable hearts will be few, because the possessor of the constitution of the neurocirculatory asthenic usually does not seek the strenuous life of the soldier. He is the type of man who avoids strenuous physical exertion and strong stimuli. Modern armies are obtained by drafting all men within certain age limits; and these more timid, less strenuously inclined individuals are taken along with the rest.

The effort syndrome is the peculiar characteristic of neurocirculatory asthenia, namely, an exaggerated response to physical exertion and emotional stimuli. Slight physical exertion produces marked dyspnea, greatly increased pulse rate, a feeling of fatigue, and very frequently pain over the precordium. Even the slight emotional stimulus of the physical examination will cause sweat to trickle down from the arm pits or stand out in beads over the foreheads, or will cause a flush to appear in the face, and the pulse rate always goes up to from 120 to 150. Many of this class have cold, clammy hands, and show a coarse tremor of the fingers or of the lower limbs during the examination. In other words, very slight causes produce great effects in these individuals. They are the men who in civil life drifted from one occupation into another. Many of them are clerks, others are sign painters, barbershop porters, any occupation that involves little exertion. Here in Texas, many of them, born as farmers, remain in this profession; but they give a history of avoiding severe bodily exertion. They almost invariably give a history of being unable to stand heat. They are subject to giddiness when forced to work in the hot sun, and are compelled to go into the shade to rest and cool off, when other men stick to their work. In other words, they are not first class men but belong to the constitutionally inferior class.

If these men are accepted by the recruiting authorities, it is noted that throughout the course of training they are continually falling out at drill, and they complain of weakness, pain over the heart, palpitation, inability to stand the hot sun, and inability to sleep after a hard day's work. They are often looked on as malingerers, and undoubtedly often they are when judged by our present standards. The company commanders like to get rid of them, transfer them, if it is impossible to get them discharged. If finally taken to the front, they are usually sent back to the base hospitals because the severe bodily exertions and emotional disturbances there are too much for them. Desire for alcohol and development of the sexual instinct have always been looked on as indicative of strength in men. As a class the neurocirculatory asthenics are not attracted by either Bacchus or Venus.

Neurocirculatory asthenia is probably not primarily a disease of the heart, but symptoms are due to an overexcitability of the autonomic nervous system, an irritable weakness of the vegetative nervous system. The rate of pulse at rest is always increased over that of normal individuals, owing to an increase in the tone of the accelerator nerves. Vagus tone seems to be normal. The increased activity of the sweat glands and the heightened response to the action of pilocarpin show that the parasympathetic system innervating the sweat glands has increased tone. The response to epinephrin is increased over that in the normal, showing increased excitability of the vasomotors. Many have marked sinus arrhythmia, showing that the centripetal vagus fibers from the alveoli of the lung are hyperexcitable. Many of these men show decided neurotic or psychoneurotic symptoms. We believe that all of the nervous symptoms can be explained on the basis of changes in the tone of the nervous systems, especially the vegetative.

In the foregoing we have been describing the most common type of neurocirculatory asthenic. At the training camps one encounters another class, less frequently. In the latter class there are no signs of constitutional inferiority. These men give a history of having done hard work, of having played games, etc., until a severe infection, usually typhoid, pneumonia or influenza, was followed by a slow and incomplete recovery. From this convalescence they invariably date their inability to undergo severe exertion. The men in this class usually appear fit to the eye, but the exercise test is followed by dyspnea and distress and a marked increase in pulse rate, which does not go down for five minutes or more. These cases show the cold, cyanotic hands, the sweating and the coarse tremors less frequently than the cases that are associated with constitutional inferiority and psychoneurotic symptoms. Tachycardia is also present in these cases when they appear for examination. They correspond to the cases of Group 2 of Oppenheimer and Rothschild.[3]

[2] Lewis, Thomas: Report upon Soldiers Returned as Cases of "Disordered Action of Heart," Medical Research Committee, 1917; Report on Neurocirculatory Asthenia and Its Management, Mil. Surgeon 42:[illegible], 1918.

The tachycardia is the symptom that draws the attention of the cardiovascular examiner to these men. The excitement of the examination and of the new environment tends to increase the pulse rate in all men; but, as stated before, the increase is greater in this class than in normal men. Of course, men having hyperthyroidism, men with high temperatures or recently recovering from infectious diseases, and men under emotional stress will also show increased pulse rate. After noting the increased rate, it becomes the duty of the examiner to classify the case. The hyperthyroid cases will show enlarged thyroid, eye symptoms and the characteristic fine tremor. They will usually give a history of loss of weight with good appetite, of much sweating and a "flying off the handle." Men recovering from infectious diseases will give the history. Many of those suffering from neurocirculatory asthenia will also give a history of infectious disease; in fact, as stated above, it would seem from our observation that typhoid fever, tonsillitis, pneumonia and influenza are often directly associated with the causation of this condition. We lay great stress on a history of inability to do hard work, wandering from job to job, precordial pain, lack of desire to play games, to swim, to skate, to take part in young men's activities, dyspnea on slight exertion and palpitation. A history of infectious disease followed by the symptoms of irritable heart is equally important; in fact, there should be no diagnosis of neurocirculatory asthenia without a typical history.

The objective examination is conducted as follows: The pulse rate is taken with the soldier standing and recumbent. The recruit is then made to hop 100 times on one foot. The pulse rate immediately after exercise and two minutes later are taken in recumbency. The typical case of irritable heart will show a marked difference between the rate recumbent and the rate standing. The heart reacts strongly to what is normally a very slight circulatory change. Hopping a hundred times is very mild exercise for the normal man, and the heart rate increases only moderately. There is only a very slight increase in breathing, and there is no distress. The circulatory asthenic shows distressing features, becomes markedly dyspneic, the pulse rate increases alarmingly, and the recruit is glad to lie down on the bed. After two minutes, the pulse rate in the normal returns to within a few beats of the preexercise recumbent rate. In fact, it usually is a few beats less, whereas, in the irritable heart, the rate does not come back within two minutes and there is often dyspnea after this period. The so-called effort syndrome, this exaggerated response to light physical exertion and the poor "come-back" is the most characteristic feature of neurocirculatory asthenia. It alone is not sufficient for the diagnosis, because in reconvalescence, after inoculation and during certain emotional states, the same exaggerated response is often encountered. Before the diagnosis is made, a very careful history must be taken and the examiner must be very shrewd in judging the timber from which men are made.

Many of the negroes come to us with the diagnosis of "heart trouble" firmly fixed in their minds. They complain of precordial or chest pain, especially when forced to work hard. There is a tachycardia and the pulse reaction characteristic of neurocirculatory asthenia, yet there is something about the case that does not impress one as genuine. The dyspnea is often very marked before exercise. In many cases, the rate of breathing becomes much less after exercise and the exaggerated dyspnea is done periodically, a rest from the strenuous contortions of the abdominal and diaphragmatic muscles being necessary. In these cases, the symptoms are overdone to the point of being grotesque. They are simply cases of simulation; but the pulse rate is up, and if one were to judge from one examination, a discharge would probably be given. We therefore insist on repeated examination, and sometimes catch the malingerer on one of his "off days."

For instance, a negro was recently sent to the cardiovascular board from his infirmary for reexamination and classification. He complained of precordial pain and pain in the back, and found it necessary to stop and rest when the drill period was long, because of "weakness" and "shortness of breath." Close questioning brought out the fact that he had a large crop of cotton at home that needed his attention. His pulse rate standing was 156, and in recumbency 124. After exercise his pulse rate went up to 156, and after two minutes rest in recumbency the rate was 124. The exercise produced dyspnea, which seemed exaggerated. It was largely produced by abdominal muscle work. He was asked to return one week later. On our arrival at the cardiovascular examining room on the appointed morning, we found him clutching a post with one arm, bent over with his other hand on the precordium, and his abdominal muscles working with his diaphragm to produce a dyspnea of almost 60 per minute, a picture of intense distress. The pulse rate standing this day was 140, in recumbency 104, after exercise 140, and two minutes later 104.

The dyspnea after exercise was great, but no greater than before We finally decided that this man should be put in a labor battalion, for his pulse rate was persistently high. We told the soldier that we had decided that he was unfit for the work of a soldier, which required a man who could keep going even when he got tired and out of breath, but that he was good enough for a labor battalion, to wield a pick and shovel and clean up latrines. We emphasized the fact that he might have to dig ditches under fire and that his only advantage over the soldier was that he could take a rest, even under fire. A surprised look came over the negro's face, and he began to beg not to be put into a labor battalion. He wanted to wear a uniform and carry a gun. He knew that he could stand hard drilling. We promised to give him another examination in fifteen or twenty minutes. In the meantime he was to sit down and rest. When reexamined, not more than half an hour later, his pulse, standing, was 88, recumbent 68, after exercise 120, and two minutes later 88. There was no dyspnea after hopping this time, and what is more important, no dyspnea of the abdominal type before hopping.

[3] Oppenheimer, B. S., and Rothschild, M. A.: The Psychoneurotic Factor in the Irritable Heart of Soldiers, J. A. M. A. **70**: 1919 (June 22) 1918.

We hope that this boy will remain "cured." We believe that the threat of the labor battalion will be a very good prophylactic measure for him and his comrades.

REJECTIONS

The cardiovascular board at Camp Travis has been turning down between 0.3 and 0.4 per cent. of all recruits at the first examination for neurocirculatory asthenia. Later on during the period of training a certain number of men are sent back to the board for reexamination and reclassification, because they have been found to be unable to stand up at drill. At the first examination it is impossible to cull out all, for there is every degree of neurocirculatory asthenia and a small percentage will become fit for the physical exertions of a soldier when carefully trained. When the Ninetieth Division, consisting of about 22,000 men, left Camp Travis for France, about 2,000 men were discarded for physical inaptitude. Of this number, the cardiovascular board picked out fifty as typical neurocirculatory asthenics, that is, about 0.25 per cent. of the strength of the division. This was not the total number of neurocirculatory asthenics with which the Ninetieth Division was embarrassed; a few had been discharged during the training period, and more had been transferred to the depot brigade as inapt for foreign service before the departure of the division. The cardiovascular board has been gradually weeding them out of the camp. They are sent to the cardiovascular board by the infirmary physicians, who well know that these tachycardias are continually being returned to the infirmaries by the company commanders, who can get nothing out of them. In fact, it has often appeared to us that the company commanders are more familiar with the symptoms of neurocirculatory asthenia than the average medical officer. We well remember the remark which one of our friends made before sailing for France with his company. He was describing and discussing the large number of men in his company who could not stand up under hard hikes, who were short winded, and lacked courage and initiative in performing athletic stunts. This officer said:

> Don't the doctors know anything about heart diseases? All these men have poor hearts. They haven't any wind; I have sent them back to the infirmary a number of times, but the doctor will never discharge them. I know they will never be any good when we get them into the trenches. I would rather have a company lacking its full quota than to have the quota made up of these men. They are the biggest handicap I have.

His remarks about the doctors were certainly justified. We have been taught to look for anatomic lesions, murmurs denoting valvular defects. Moreover, there was a tendency in the early period of the formation of our army to keep down the number of rejections at all costs, and of course the cost was paid by lowering the quality of the men. When the cardiovascular board first began its examinations at Camp Travis it was impossible to have men discharged from this camp for neurocirculatory asthenia which was termed "simple tachycardia." Consequently these men got into the division. Many of them had to be transferred back to the depot brigade and are being culled out of that organization gradually at present. Some got across and will have to be turned back on the other side. The manual of instructions for the examining physicians says that a constant rate of 100 or more in recumbency should disqualify. It is a characteristic of the irritable hearts that the difference between the standing and recumbent rate is very large, and many of the typical cases of neurocirculatory asthenia with rates above 120 in standing will go down below 100 on recumbency; besides, the pulse rate alone can never be the only criterion for discharge. The amount of distress after exertion, the history of the case and the appearance of the men are all as important as the pulse rate. At present the cardiovascular board at Camp Travis has carte blanche in discharging its cases. Two hundred and eight men, or 0.38 per cent. of the total number examined, have been discharged for neurocirculatory asthenia. Many of those that we felt should have been discharged during the earlier months of our activity at Camp Travis have since been discharged, either as members of the Ninetieth Division or as holdovers in the training battalion or depot brigade. Some who should have been discharged have no doubt been transferred to other camps. Altogether, we feel that about 0.5 per cent. of all the men arriving at Camp Travis should be turned down for neurocirculatory asthenia. This figure agrees very well with the estimate we have made from the number of cases of neurocirculatory asthenia in the Ninetieth Division, men who were given a fair trial and found wanting after one or two months' service. We want to emphasize again that very few of these men are any good in military service, and we do not believe that very many of them can be made first class soldiers, capable of severe bodily exertion, even when carefully trained. At present there are no special companies for properly training this class of men at Camp Travis, and the only proper procedure is to discharge them as soon as there is certainty of their condition and get them out of the Army. This type of man is naturally disinclined to exert himself. He gets stamped as a malingerer, and very possibly he is of that type; but under no circumstances should the Army be punished for the shortcomings of the man. The Army needs nothing but first class men, and these men are all of them third raters. They are the men who do not succeed in life. They are constitutionally inferior.

There are a certain number of men who, after passing the cardiovascular examination at the camps will pass through a training period as excellent soldiers, and they will go through a part of the campaign in Europe, making good records. Shell shock, gassing, infections attendant on life in the trenches, and lack of sleep, coupled with severe bodily exertion, will make neurocirculatory asthenics out of them. They are of a different type, however, and many, though not all of them, after rest and careful physical training will be returned to their regiments as good or fair soldiers. This type differs from the constitutionally inferior type, which can be culled out at the preliminary examinations. Possibly there is in these cases a certain amount of exhaustion of the myocardium. I saw a large number of these individuals in 1914 at the heart station established by the German army in Nauheim. Many showed a very slight enlargement of the left and right auricular shadows when careful orthodiagrams were made. Electrocardiograms also indicated a slight right ventricular preponderance. These men had been students, office men, business men and in some cases farmers, who had been called from a more or less sedentary life into immediate active service or whose preliminary training had been insufficient for the terrific physical exertion they were called on to undergo. They gave a history of having been forced to march up to 40 kilometers a day in the advance toward and the retreat from the Marne with insufficient nourishment and sleep, and burdened with heavy packs. This resulted in symptoms of breathlessness and precordial pain, inability to sleep, and a soft systolic murmur at the apex which we believe of little significance, and this very slight bulging of the left and right auricle shadows of the heart. The orthodiagraphic work was done by a man who helped to develop orthodiagraphy with Mortiz and who has done this work in an extremely careful way in thousands of cases. There was no question of there being a slight rounding of the figure of the heart, and there was no question about many of these cases showing a slightly depressed Q R S group in Lead I and a high Q R S group in Lead III, all indicative of a period when myocardial insufficiency had been present with regurgitation back through the mitral orifice. Under proper treatment many of these men apparently recovered full myocardial efficiency. It is interesting to note that there was no change in the orthodiagrams or electrocardiograms after the return of apparently good function.

There are a few cases of tachycardia that cannot be classed as hyperthyroidism because the other symptoms of this condition are not to be found. Neither can they be classed as neurocirculatory asthenia, for the typical history and precordial pain is not present. Usually the pulse rate does not go down as far in recumbency as it does in the typical cases of irritable heart. We classify such cases as persistent tachycardia if it is present at repeated examination, and then discharge the men; for it is evident that such hearts "will not stand the gaff." Evans demonstrated some years ago that a heart consumed more energy doing the same amount of work per minute when the pulse rate is rapid than it consumes when the rate is slow. For this reason a heart working at a rapid rate becomes exhausted more rapidly than a heart doing the same circulatory work, but at a slower rate. A slow rate is the characteristic of the well trained athlete's heart. It is a rule that men with persistent tachycardia cannot hold out, other things being equal. The possessor of a heart rate persistently above 100 should be discharged or given deferred classification.

CONCLUSIONS

1. The incidence of aortic insufficiency in Texas and Oklahoma is about 0.1 per cent. between the ages of 21 and 31.

2. Uncomplicated mitral insufficiency of endocarditic origin is comparatively rare, being probably not much greater than 0.1 per cent. for men between 21 and 31.

3. Accidental systolic murmurs at the apex are very common, about 3 per cent. of all men showing them, and they are of practically no significance, unless accompanied by signs of hypertrophy and increased pulmonic pressure.

4. Neurocirculatory asthenia is the most important cardiovascular disease in our army. At least 0.5 per cent. of all the drafted men should be rejected for this condition before the various divisions sail for France.

5. The incidence of mitral stenosis is about 0.02 per cent.; of idiopathic hypertrophy, about 0.01 per cent.; of hypertension, 0.02 per cent., and of hyperthyroidism, 0.015 per cent.

BLOOD-CLOT DRESSING IN MASTOIDECTOMY

MODIFIED TECHNIC WHICH ASSURES PRIMARY PAINLESS HEALING WITHOUT DEFORMITY—PRELIMINARY REPORT

GEORGE E. DAVIS, M.D.
NEW YORK

I wish to add my observations and experience to those of Blake, Reik, Holmes and others in perfecting the technic of the blod-clot dressing in mastoidectomy, a method, I feel, that is destined to revolutionize the after-treatment of mastoiditis.

Recently in a historical review of the institutes of surgery, Sir Berkeley Moynihan[1] observed that "a discovery is rarely the work of one mind. It is one observation added to another that makes the supersaturated solution from which the crystal of truth at last precipitates." This observation was evoked by an allusion to the respective share or credit of Lister and Pasteur for the discovery of the antiseptic system. Moynihan added that "Lister never ceased to give credit to Pasteur for his share in the work that led finally to the development of the antiseptic method."

The foregoing citation is peculiarly apropos to the theme of my text, since the key to the successful employment of the blood-clot dressing in mastoidectomy is wholly dependent on a perfect antiseptic technic, especially as we are dealing always with an infected wound in mastoiditis. The value of the "organized blood-clot" in the healing process was discovered by the greatest of original observers of pathologic conditions, the immortal John Hunter. Long afterward the technic of the blood-clot as a dressing was exploited and made practical use of in surgery on the continent by Schede and subsequently, in this country, by Halsted, Senn, Ochsner and others.

Credit is due Blake of Boston, who, at the suggestion of Sprague of Providence, R. I., first employed it in mastoidectomy. But especially to Reik of Baltimore must be ascribed the most credit for the development or popularizing the blood-clot dressing in mastoidectomy.'

Briefly, the technic of the blood-clot dressing as originally practiced in mastoidectomy was to eradicate as thoroughly as possible all diseased tissues, observing strict asepsis, and the blood-clot was admitted at the time of the operation.

The cardinal error of this technic was brought home to me by an observation and experience I had in a radical frontal sinus case which I reported, with the presentation of the patient, to the New York Academy of Medicine in March, 1918, and, by the way, the first and only case on record, so far as I know, in which the blood-clot method was used in this location—the frontal sinus.

In this case a radical Killian operation was done. After removal of the anterior sinus wall, it was observed that the entire sinus floor was necrosed and that there was the complication of a foul postorbital abscess. The necrosis extended so far into the orbital arch that it was necessary to remove this also. The postorbital abscess cavity and the sinus cavity were packed with a continuous strip of iodoform wool and the wound closed, one end of the packing being left protruding from the temporal angle of the wound and the other end coming out through the nose. In twenty-four hours this strip of wool (gauze will answer same purpose) was withdrawn by traction on the nasal end till it was taut to the temporal end, when it was cut at the nasal end, this single strand being left to block the escape of the blood (occasioned by the removal of the rest of the packing) which filled the sinus cavity, preserving the contour of the orbital arch and sinus wall.

---

[1] Moynihan, Sir [illegible]: Brit. Me[illegible] in the War, 1914-1917, Tr. Brit. Med. A.

Twenty-four hours later the remaining strand of wool was removed. No further treatment was made save an oil spray in the nose during the week the patient remained in the hospital, when he went home healed without deformity and without discharge.

The operation was performed Nov. 9, 1917, and the patient remains well.

It occurred to me that the blood-clot dressing proved a success in this case simply for the reason that the infected wound cavity was first made aseptic by antiseptics at the time of the operation and the iodoform packing preceding the admission of the blood-clot. Therefore the deduction was natural that if an infected frontal sinus wound could be made sterile by antiseptic dressings preliminary to the introduction of the blood-clot, the same could be accomplished in an infected mastoid wound.

From that date I decided to modify the technic of the blood-clot dressing in mastoidectomy, for I was convinced that the incomplete success of the blood-clot dressing as originally adapted and practiced must be charged to a cardinal error in surgical technic: introduction of the blood-clot into an infected wound.

Holmes,[2] in an address on this topic before the Ninth International Otological Congress at Boston in 1912, said that "the success of the blood-clot method in a wound like the mastoid, which can never be made entirely aseptic, depends primarily on eliminating as nearly as possible all infective matter, and secondly on the bactericidal properties of the blood."

From the operative standpoint, therefore, the most expert surgeon may not hope to remove all diseased tissue and bone. He may attain such a degree of success in some cases that the antiseptic properties of the blood may resist any infection that remains, but not so in all cases.

Physiologically considered, the blood-clot dressing as originally conceived was based on the principle that if blood is admitted into a sterile wound of the soft or bony tissues, the clot will organize and facilitate healing, with obliteration of the dead space.

Reik's[3] review of this method from a physiologic point of view probably is familiar to most otologists. Unfortunately the application of this technic in mastoidectomy was not so happy as its conception, nor altogether a rational surgical procedure. While we were admonished that strict sterility of the wound preliminary to the admission of the blood-clot was essential to success, we were advised to do the impossible—to eradicate thoroughly all infected and diseased tissue. Moreover, antiseptics were tabued, only asepsis being allowed.

Therefore, without the aid of the rather marked inherent antiseptic principle contained in the blood-clot, even the best operators with perfect hospital facilities, trained attendants, etc., could not have attained the limited success they did.

What I consider to be a perfected technic that renders the mastoid wound entirely aseptic is the thorough sterilization of the wound with antiseptics at the time of operation, followed by a packing of iodoform gauze that is permitted to remain for twenty-four hours before the blood-clot is admitted.

My technic is as simple as it is effective:

All infected and diseased tissue possible consistent with safety is exenterated. In simple mastoidectomy after thorough exenteration of the mastoid and the establishing of free communication from the antrum into the tympanum, a free incision of the membrana tympani is made and with a piston syringe the tympanum is flushed from the mastoid through the canal with 3 per cent. iodin solution and then with warm alcohol followed with warm sterile physiologic sodium chlorid solution. Then the mastoid is packed with iodoform gauze and closed to the lower angle save for a space that will permit one end of the gauze to protrude.

In twenty-four hours the packing is withdrawn and the bleeding occasioned by its withdrawal allowed to fill the wound cavity. If enough blood is not forthcoming, a nick or cut with a knife or the scissors is made in the angle or margin of the flap to supply sufficient blood to fill the cavity.

The subsequent treatment after turning in the clot in simple mastoidectomy is to close the lower angle of the wound with adhesive plaster with removal of the sutures on the second or third day.

Silkworm gut is used for suture material in this work, and before removal a 3 per cent. solution of iodin is applied to prevent possible infection of the blood clot. The postauricular wound heals in a few days, and as the blood clot supports the soft tissues, there results little or no depression or deformity. The middle ear usually ceases to discharge in a week or ten days, though the time occasionally may be longer.

Following exenteration in radical mastoidectomy, the postauricular wound is closed completely and the mastoid cavity, tympanum and canal are packed with iodoform gauze through the enlarged meatus. The next day the gauze packing is removed and the entire cavity, to the level of the meatus, allowed to fill with blood occasioned by its removal. If sufficient blood is not thus obtained, the tragus is nicked or cut for the balance. The meatus is covered with a film of cotton or layer of sterile gauze, over this sterile petrolatum or other lubricant, and over all adjust an outer dressing which is changed daily. Sutures are removed on the second or third day. Before removing sutures I always apply 3 per cent. iodin along the wound margin and over the sutures, to avoid infecting the deeper tissues and clot as they are being drawn out.

The clot begins to disintegrate in three or four days. The disintegration may be encouraged by the insertion of small gauze or cotton wick-drains saturated with a 10 per cent. solution of phenol in glycerin.

Usually the absorption or disintegration of the clot is complete in two or three weeks, when the bony cavity should be covered with a thin, pink, granular membrane which later becomes smooth, lustrous and fibrous. Should exuberant granulations appear on the median tympanic wall over the oval and round windows, 50 per cent. silver nitrate solution is applied, after the surface has been dried.

I wish to emphasize the importance of thoroughly drying the granulation surface before applying strong silver solutions. This little point in technic prevents pain and reaction, as moisture is essential to conduction of sensation unless undue pressure is made.

The support furnished by the blood-clot before it disintegrates prevents sagging and deformity of the postauricular wound; and as healing is primary, no long, painful packing after-treatment must be endured to wreck the patient's nerves, body and purse.

A short time ago a woman from a neighboring city, who had undergone a simple mastoidectomy nearly three months previous to a visit to New York, was referred to me by a confrère for further packing while here, as there was still discharge posteriorly from the mastoid and also from the tympanum through the canal. She informed me that she had lost much weight and was a nervous wreck under the care of a nerve specialist, all because of the torturing packing after-treatment. Often she was in bed for a day following a dressing.

[3] Reik, H. O.: The Blood-Clot Dressing in Mastoidectomy Considered Physiologically, J. A. M. A. **56**: 935 (March 31) 1906.

The advantages of the modified technic of the blood-clot dressing are:

1. The opportunity to sterilize the wound with antiseptics at the time of operation.

2. The completion and maintenance of this sterility by the iodoform gauze packing of the wound for twenty-four hours, which prevents the infection from the deeper tissues that may occur from the operative reaction drainage when the clot is inducted at the time of the operation.

3. Its simplicity and effectiveness, which enables the average surgeon to use it successfully in or out of hospitals.

REPORT OF CASES

Numerically, the cases in this initial report are far too few to permit sweeping deductions. But with practically a hundred per cent. of primary healing without deformity, quick convalescence, no painful after-treatment, and marked improvement of hearing, even in this very limited series of both acute and chronic cases, with the exception of one acute case complicated with large subperiosteal and perisinuous abscesses, plus a sinus thrombosis in an alcoholic and syphilitic that healed with but slight deformity at the lower angle of the wound where the clot broke down, I am prompted to make this early report, at what seems to be an opportune time, as mastoiditis is prevalent among our soldiers in camp and field. Excepting the acute case with the sinus complication when, as in brain and meningeal complications, the advocates of the blood-clot method advise leaving the wound open, my percentage is perfect in eight consecutive cases from May 19 to August 15.

Case 1.—M. L., aged 30 years, underwent simple mastoidectomy, May 19, at the New York State Hospital, Central Islip, L. I., for acute mastoiditis complicated with a large cervical glandular abscess. The mastoid wound was packed with iodoform gauze and closed to the lower angle. The dressing was removed in twenty-four hours and the mastoid cavity allowed to fill with blood and the lower angle of the wound closed. The mastoid wound completely healed and there was no discharge from the ear at the end of seven days.

Case 2.—B. H., girl, aged 11 years, was admitted to the Polyclinic Hospital, June 5, on account of reinfection following an acute mastoidectomy about six months before. A simple mastoidectomy was performed. The tympanum was flushed with alcohol followed by salt solution. The mastoid wound was packed with iodoform gauze and closed to the lower angle. The gauze was removed next day, the wound was allowed to fill with blood, and the lower angle was closed. The postauricular wound healed in six days, but the ear was not dry until two weeks later.

Case 3.—L. C., boy, aged 9 years, admitted to the Polyclinic Hospital, July 3, had a radical mastoidectomy following incomplete operation five months before. The postauricular wound healed in five days. As the eustachian tube failed to close, some mucous discharge remains at the tympanic orifice.

Case 4.—J. C., girl, aged 5 years, admitted to the Polyclinic Hospital, July 4, was operated on the following day. A simple mastoidectomy was performed, the tympanum was flushed with alcohol followed with physiologic sodium chlorid solution, and the mastoid wound was packed with iodoform gauze and closed to the lower angle. Next day the packing was removed, the clot admitted, and the lower angle of the wound closed. The mastoid wound was healed in five days, and the ear was dry in two weeks.

Case 5.—C. G., man, aged 38, admitted to the Polyclinic Hospital, July 19, had acute mastoiditis complicated with a large subperiosteal abscess and a large perisinuous abscess exposing it over a large area, plus a sinus thrombosis. A simple mastoidectomy was performed; the tympanum was flushed with alcohol and salt solution, the sinus incised and the clot above and below turned out until free bleeding occurred. The sinus and mastoid wounds were packed with iodoform gauze and the upper half and posterior extension of the wound closed. In this case the gauze was allowed to remain four days, when it was removed and the wound inspected and packed again for twenty-four hours. Then the packing was removed and the clot inducted, the blood being obtained by means of a deep nick or cut with scissors in the lower end of the anterior wound flap. The lower half of the mastoid wound was then closed by means of adhesive strips, an outer dressing applied, and this changed daily. Six days later, or on the eleventh day following the operation, the ear was absolutely dry and the mastoid wound apparently sound, as the surface was healed. At this stage, however, the lower angle of the wound with that portion of the clot broke down, and after ten days finally healed with only a slight depression. In the meantime the ear remained dry.

This case is unique, and I regard it phenomenal, in that all operators who have employed the blood-clot dressing are agreed that in sinus, brain and meningeal complications the cases should be treated by the open method and packed. Moreover, this patient was alcoholic and syphilitic.

Case 6.—S. H., woman, aged 28, admitted to the Polyclinic Hospital, July 30, and discharged, August 7, had a secondary radical mastoid operation. The posterior wound healed in five days, and the ear was dry in seventeen days.

Case 7.—M. V., man, aged 26, admitted to the Polyclinic Hospital, August 2, and discharged, August 6, had a radical mastoid operation nineteen years previously, but the wound never healed. Moreover, there was a large opening the size of a dime behind the ear. A secondary radical operation, plus a plastic operation to close the postauricular opening, was performed and the mastoid wound cavity packed with iodoform gauze through the external meatus. The following day the iodoform gauze was removed and the clot inducted. The posterior wound healed in five days, when the patient left the hospital. One week later with the disintegration of the clot and the lack of its support, the posterior wound in this case broke at one point on account of the lack of vascularity of the scar tissue in the flaps from the first operation. Under local anesthesia the scar tissue was trimmed out and the margins of the flaps sutured. Healing occurred in five days but with slight depression.

Case 8.—E. N., woman, aged 28, had a classic radical mastoid operation at the New York State Hospital, August 4. The wound cavity was packed with iodoform gauze, which was removed next day and the clot admitted. The wound healed by primary intention and the ear was dry in fifteen days.

Case 9.—J. H., man, aged 26, was operated on at the New York State Hospital, Central Islip, L. I., August 15, secondary to a radical operation ten years before, which never healed or ceased to discharge. During the operation the sinus was injured and on this account the iodoform packing was left in for three days, when it was removed and the clot inducted. Primary healing of the wound occurred, and the ear was dry in twenty days.

42 West Seventy-Seventh Street.

Tuberculosis and War Risk Claims of Soldiers.—According to Col. Charles E. Banks, chief medical adviser of the War Risk Insurance Commission, approximately 50 per cent. of all claims for war risk compensation are based on tuberculosis. In about 50 per cent. of the soldiers discharged from the Army for disability, tuberculosis is the cause.

THE VALUE OF CHEST FLUOROSCOPY

F. E. DIEMER, M.D. (Hot Springs, Ark.)
Captain, M. C., U. S. Army

AND

R. D. MacRAE, M.D. (St. Maries, Idaho)
Lieutenant, M. C., U. S. Army

CAMP LEWIS, AMERICAN LAKE, WASH.

In the first draft quota (of about 50,000 men) inducted into the military service at Camp Lewis, the roentgen-ray staff of the base hospital made about 5,000 fluoroscopic chest examinations, with the cooperation of the president of the tuberculosis examining board. As our equipment and organization at that time were not adequate, we have no data to present covering this work.

April 1, 1918, we installed a fluoroscopic outfit at the mustering office for performing work there, in conjunction with the tuberculosis and the cardiovascular boards. It should be observed that the fluoroscopic examinations undertaken were intended not only to confirm the clinical diagnosis of tuberculosis but also for the recognition of abnormal chest conditions that might exist and be overlooked on physical examination. In the event that any abnormality was discovered on screen examination, the man was thereupon referred to specialists for reexamination. This proved of decided advantage to the president of the tuberculosis examining board on account of the fact that noise and haste do not improve the ability of the clinical examiners.

From April 1, 1918, to Aug. 10, 1918, we screened 13,893 chests. Our equipment consists of the special type 3-inch self-rectifying Coolidge tube actuated by the standard bedside unit. The Edwards screen is used and affords a very sharp, contrasty illumination. We have found that in order to get the maximal diagnostic assistance, first class equipment is essential. The tube must afford the smallest focal spot and the screen must be the most brilliant with no lag.

To achieve greater efficiency it was necessary to adopt a standardized nomenclature and routine. According to our routine, ten patients, stripped to the waist, are admitted simultaneously to the fluoroscopic room. After completion of each examination a blue light, suspended over the fluoroscope, behind the operator, controlled by the stenographer who records the findings, is turned on to permit rapid change of patients and to facilitate the penciling of areas on the chest requiring reexamination or reference to the cardiovascular board.

The stenographer at the mustering office makes two typewritten copies of each dictation, with the name of the operator on each, one for filing with the tuberculosis examining board, the other for the roentgen-ray department. The findings are also tabulated in a ledger to check the work of each operator.

The amount of fluoroscopic work that can be properly done by one operator is limited. An efficient fluoroscopist should average sixty examinations an hour. Experience has shown, however, that to avoid undue fatigue he should confine himself to a maximum of two hours, the best procedure being to divide the work into two periods of an hour each, one in the morning and one in the afternoon.

The draft quotas have arrived at Camp Lewis at the rate of about 10,000 a month, and have been examined, for the most part, during the first ten days, averaging 1,000 recruits a day. Of these about 250 have been eligible for screening. Our staff has been obliged to work at top speed averaging ten days a month. During the subsequent twenty days the daily fluoroscopic examinations have been from forty to sixty, including late arrivals, reexaminations of suspicious cases, and chest fluoroscopies of all pneumonia, influenza and measles patients.

WHEN FLUOROSCOPY SHOULD BE UNDERTAKEN

Our experience has demonstrated that practically 25 per cent. of all men between the ages of 21 and 31 should be subjected to thorough examination for the detection of possible chest abnormalities. Such examination should be undertaken in cases presenting any of the following points, which have been formulated by the president of the tuberculosis examining board:

A. History of prolonged contact with, or death in the family from, tuberculosis.

B. Inability to work because of ill health.

C. Well defined history of previous pleurisy, pneumonia, frequent or protracted colds, typhoid fever, or any other past illness of prolonged duration which might have constituted (or indicated) tuberculosis, such as prolonged cough accompanied by expectoration, hemorrhage from the lungs or expectoration of bloody sputum, loss of weight or strength, fatigue, night sweats, etc.

D. Existing cervical adenitis, tuberculosis of the bones or joints, or rectal fistula.

E. Every asthenic case and all cases in which the physical condition is manifestly below par, or giving evidence of lack in stamina or resistance.

F. All cases of chest deformity, scoliosis, kyphosis, funnel chest, barrel chest and flat or pigeon breast.

G. All cases in which physical examination reveals:

1. Impaired resonance on percussion.
2. Increased transmission of voice sounds, over areas in which these are not normally increased.
3. Abnormal breathing, such as sharpened vesicular or rough inspiration, over areas in which this is physiologically abnormal, even though no râles are detected.
4. Râles.
5. Fixation of the lung border.

RECOGNITION OF TUBERCULOSIS

Out of a total representation of 13,893 chest fluoroscopies, 425 patients were rejected on account of pulmonary tuberculosis. We are unable to claim recognition of all these cases, but a considerable percentage have likewise failed to be recognized by the clinical examiners of the tuberculosis board, including a number of unmistakable cases which have been detected by the screen. The very thorough performance of this system is evidenced by the fact that a very few cases of tuberculosis, overlooked in our mustering office work, have been admitted as such to the base hospital after being mustered.

We are not only convinced that, with careful examination, very few cases of tuberculosis will pass the roentgenologist unrecognized, either as such or presenting definite abnormalities that prompt him to send the subject to the special examiners, but also know that fewer cases will thus be overlooked than by clinical examination, particularly when the clinician is unable to eliminate haste and noise. The physical signs in the case of chronic and inactive fibrocaseous tuberculosis are minimal and susceptible of recognition only by the experienced clinician, but the screen findings offer unmistakable evidences of the abnormality in question.

We have been very careful not to diagnose tuberculosis unless the roentgenologic evidence is unmistakable. The argument appears to be current among clinicians that screen findings do not offer incontrovertible evidence of a tuberculous condition, and that a positive diagnosis of tuberculosis in the absence of excavation is impossible. We are of the opinion that this view arises from the lack of familiarity with the technic of chest fluoroscopy or because of an inferior tube and screen. The finding in certain types of pneumonia present almost, although not the same, picture.

The percentage of unmistakable cases of tuberculosis overlooked by the clinicians and detected fluoroscopically is difficult to estimate accurately, since a great many histories mention only slight impairment, râles that are not constant, diminished breath sounds, slightly increased resonance, and fixed diaphragm and other physical signs, which, while they may be associated with tuberculosis, are not necessarily symptomatic of such process. In such cases, in the absence of definite notation of a tuberculous process or of its location and other relevant data, we have been inclined to give the clinicians due credit. Such conditions, in the event of the tuberculous process being inadequately described, or slightly doubtful and not susceptible of verification by the fluoroscopist owing to the lack of time and other factors, we have classed as suspected or as extremely suspicious, depending on the degree of abnormality accurately described by the fluoroscopist. Our screen findings in connection with 425 cases of rejection on which our discussion rests we have thus tabulated:

Unmistakable pulmonary tuberculosis—clinical verification unnecessary—248 cases, or 58.3 per cent. Extremely suspicious of pulmonary tuberculosis—clinical verification necessary—89 cases, or 20.9 per cent. Suspicious—clinical verification necessary—31 cases, or 7.2 per cent. Abnormalities in illumination, haziness (general or localized) combined with diaphragmatic limitation, adhesions, marked calcification areas, etc.—clinical verification essential and necessary—32 cases, or 7.5 per cent. Unrecognized by the fluoroscopist (no abnormality whatever noted), 13 cases, or 3.06 per cent. As regards our cooperation with the clinicians in connection with chest examinations, the following supplementary comments may be made: A great many subjects may be returned for special clinical reexamination even when the screen has detected only vague abnormal shadows, such as slightly reduced apical illumination or increased visibility of the secondary bronchi. Special attention is directed not only to the different degrees of illumination but also to the position of the diaphragm, heart and trachea, in connection with the various degrees of scoliosis, with a view of enabling the clinician better to account for the increased vocal fremitus, bronchial breathing, etc., associated with those cases.

ADVANTAGES OF FLUOROSCOPY

We come to the consideration of the relative advantages of fluoroscopy and the reason the highly important character of its rôle in chest examination should receive more widespread recognition than heretofore. By the way of preface it may be observed, once for all, that this report is submitted as a plea for a more thoroughgoing use of the fluoroscope in wholesale chest examinations.

In determining the chronicity of a given lesion, observation of the diaphragmatic excursions and separation is a factor of the first importance. The greater the area of parenchyma destroyed by the tuberculous process, the greater is the degree of lagging presented by the corresponding portion of the diaphragm in deep inspiration. The same holds true of the intercostal separation. It is difficult to ascertain even with the use of stereoscopic plates the exact location of a pleurodiaphragmatic adhesion. Furthermore, as many subjects are apparently unable to inspire deeply, a plate does not show the diaphragm well separated, whereas a definite idea of the excursion and separation is obtained by directing the patient to cough violently behind the fluoroscopic screen.

The extent of pleuropericardial adhesions can be determined more definitely by the screen method, as the heart excursion on deep inspiration can be estimated. Encapsulated pleural effusion can be localized about as readily by fluoroscopy as by stereoscopic plates, as the oblique view is obtainable and as the nearer the shadow is to the tube the larger it appears; and vice versa, if the shadow in question is larger when the patient is facing the operator than when turned around, the shadow is posteriorly situated. An oblique view determines its proximity to the chest wall. Also if fluid is not tightly encapsulated or is free on the pleural cavity, its upper level maintains a parallel plane with the floor when the patient flexes his body to the right or the left. This is also obviously true of lung abscesses and excavations that contain fluid.

We have on several occasions been at a loss to differentiate a uniform interlobar thickened pleura from a localized pleural effusion, and determined the exact condition only after both screening and roentgenography. Excavations that do not contain fluid almost always "light up" on coughing and are thus differentiated from circular pleuritic adhesions. Retraction or displacement of the heart, mediastinal contents and trachea (if only slight) are more definitely recognized by fluoroscopy, because not even the most carefully trained manipulator will uniformly secure the correct relation between the patient and plate; and if the tube is centered ever so slightly to either side of the midvertebral line, the distortion is very marked. In making many plates daily this will happen frequently. Also the patient may assume a scoliotic position with consequent lessened degree of illumination of the corresponding apex.

The posterior mediastinum is readily viewed by turning the patient obliquely and should invariably be done. Dilatation of the aorta, posteriorly, is not even recognized by stereoscopic plates. The screen is particularly to be preferred to plates in cardiovascular examinations. Orthodiaphragms, accurately made, show the exact cardiac area with no distortion or exaggeration whatever. We have discovered several cases of marked dilatation of the aorta that showed very few clinical signs; three cases in particular showed no evidence of abnormality except tracheal tug and accentuation of the second aortic sound on careful clinical reexamination.

It is very important to observe the degree of illumination of the apexes, the diaphragm being cut down to a horizontal rectangular slit and both viewed at once, the patient's head being directed forward with the back to the operator and the screen. The slightest difference in the degree of illumination should be carefully noted, it being remembered that slight increase in blood or fibrous tissue causes considerable haziness of the apex. Occasionally a brilliant illumination of a tuberculous apex will be seen, the result of compensatory emphysema. This phenomenon accompanies old fibrous processes, particularly those centrally located, the surrounding air sacs becoming dilated. Scoliosis from contracture of the chest wall will decrease the degree of illumination.

ABNORMALITIES DETECTED

There were in the whole series five cases of unmistakable bronchiectasis detected by the screen and verified by the plate and the clinician. The characteristics are as follows: There is a marked increase in density along the course of the secondary bronchi, the result of fibrous tissue changes. The dilated spaces in the bronchi vary greatly in size and shape and are observed as clear areas, rather circumscribed as to outline, either cylindric, oval, fusiform or presenting a sacculated appearance, resembling a bunch of small grapes, depending on the size of the secondary bronchi involved and the degree of obstruction.

One contingent of stockmen from an alkali district presented a very marked increase in visibility of the bronchovesicular tree, the result of dust deposit. We returned a large percentage of these men for reexamination by the special clinical examiners, and the clinical symptoms were particularly negative. Pneumonoconiosis is readily recognized as an abnormality but is differentiated from the chronic bronchitis and peribronchial tuberculosis only by plates and clinical study. Of the 425 cases, eight presented a unilateral pleural effusion. The condition was very chronic, and without exception the patient was unaware of the condition. We have studied four cases of spontaneous pneumothorax. We have found that about one man in 3,000 has a complete visceral transposition. We have in every case determined the stomach transposition by giving barium or observing the location of the gas bubble. In one case, pleuropericardial adhesions had rotated the apex forward and to the right, presenting clinically a cardia dextra; but the true condition was readily determined by the screen. Forty-one cases showed retraction of heart or trachea, which was very marked. Retraction was not always mentioned if the case was unmistakable, on account of necessity for haste.

In our work at the base hospital, we have detected one case of undoubted metastatic sarcoma of the lungs, presenting diffuse lymphatic distribution in contradistinction to circumscribed changes in the lung parenchyma. In our series of 18,893 examinations, many postpneumonic abnormalities were detected. These consisted of pleural thickening, interlobar adhesions (found for the most part on the right side and evidently anteriorly between the upper and middle lobe), pleurodiaphragmatic and pleuropericardial adhesions, organized encapsulated pleural effusions, and mediastinal retractions and displacements, the result of adhesions. Also, many cases were referred to the cardiovascular board on account of abnormality in configuration of the heart and mediastinal silhouettes. Two identical cases of diaphragmatic hernia were found, in which a much dilated diverticulum of the splenic flexure was present in the chest cavity. Extreme atelectasis was present with clinical findings that varied, depending on the quantity of gas in the diverticulum and consequent pressure on the lung. The condition in each case followed injury to the diaphragm, the result of rib resection.

CONCLUSION

We wish again to recall that fluoroscopy should not be considered an adjunct in chest diagnosis, but should primarily be used to detect chest abnormalities, especially in wholesale examinations when the clinicians are compelled to devote only a few minutes to each subject.

PNEUMOBACILLI AS COMPLICATING ORGANISMS IN INFLUENZAL PNEUMONIA *

H. J. NICHOLS, M.D.
Lieutenant-Colonel, M. C., U. S. Army
AND
C. O. STIMMEL
Captain, S. C., U. S. Army
WASHINGTON, D. C.

The bacteriology of the pneumonia of the recent epidemic has dealt, principally, with influenza bacilli, pneumococci and hemolytic streptococci, but several other organisms have also probably played a part in producing the complicated lung lesions. In this note, we wish to call attention to the *B. mucosus-capsulatus* group. The importance of recognizing these organisms is twofold: (1) In some cases they have a pathologic significance; (2) in many other cases they are probably harmless or terminal invaders; but in smears and sections, they may be mistaken for influenza bacilli.

No final answer has apparently yet been given to the problem of correlating the unusual lung lesions of this epidemic with the bacteriologic findings. Without entering into a full discussion of the subject, we may say that our experience, which includes cultures from lung punctures made during life, has led us to adopt the following working hypothesis: Influenza bacilli, so called at least, are the primary cause of the bronchiolitis and hemorrhagic pneumonia. In uncomplicated cases, the patient recovers or dies without any other specific lesion. But uncomplicated cases are rare, and secondary invasion usually occurs by pneumococci, streptococci or other organisms that may happen to be in the nose or mouth. These organisms produce their specific tissue reactions which, however, are not always typical on account of the underlying influenzal lesions. Pneumobacilli produce a patchy consolidation which, by coalescence, resembles that of lobar pneumonia.

Our attention was first directed to the *B. mucosus-capsulatus* group by the findings in a patient who died early in the epidemic. The case was a typical one of pneumonia following influenza. The lungs showed a diffuse hemorrhagic pneumonia with patches of consolidation, especially in the lower part of the left lower lobe. Cultures from the lung and heart's blood gave only the Friedländer type of organisms. Sections showed a large number of gram-negative bacilli in the alveoli. Sections of the hemorrhagic areas were typical of the congestion, hemorrhage and edema of the epidemic; sections of the consolidated areas showed the alveoli filled with desquamated epithelium and leukocytes of the mononuclear type.

---

* From the Laboratory Service of the Walter Reed General Hospital.

A series of inoculations was then made from consecutive necropsies of 1 to 2 c.c. of lung juice, subcutaneously and intraperitoneally, in guinea-pigs. Twenty-seven out of thirty animals died in from twenty-four to forty-eight hours with an infection of the Friendländer type. The same group of organisms was found in smears and cultures of the lung juice, along with pneumococci, streptococci and staphylococci, often in very large numbers.

The organisms of this group are known to be frequent inhabitants of the nose, and in a series of fourteen postmortem sinus examinations, they were found seven times, most frequently in the sphenoid sinuses.

These findings have led us to regard, with some qualifications, the significance of cultures of the lung after death, as many organisms can apparently invade very quickly. Cultures of material obtained by lung puncture, made during life, have more significance. In a series of ten such cultures, we have found the influenza bacillus seven times, pure in five cases and combined with pneumococci, Types II and II irregular, in two cases; in one case, pneumococcus Type I was found alone. Two cultures were sterile.

Out of ten guinea-pigs inoculated with material from ten other lung punctures, made during life, one died of Friedländer infection.

We have spoken of these organisms as a group, as subdivisions by sugar reactions do not seem entirely reliable. Reactions in nine strains were as shown in the accompanying table.

SUGAR REACTIONS OF B. MUCOSUS-CAPSULATUS GROUP, WITH HISS SERUM WATER

No.	Fermentation Tubes			Mannite	Maltose	Dextrin	Inulin	Salicin	Litmus Milk
	Glucose	Lactose	Saccharose						
1	+ 40%	+ 40%	+ 5%	+	+	+	0	+	+
2	+ 30	+ 20	+ 10	+	+	+	0	+	+
3	+ 50	+ 10	+ 100	+	+	+	0	+	+
4	+ 20	+ 20	+ 40	+	+	+	0	+	+
5	+ 40	+ 40	+ 0	+	+	+	0	+	+
6	+ 30	+ 40	+ 0	+	+	+	0	+	+
7	+ 30	+ 40	+ 0	+	+	+	0	+	+
8	+ 40	+ 40	+ 0	+	+	+	0	+	+
9	+ 20	+ 20	+ 0	+	+	+	0	+	+

These organisms are gram-negative, nonmotile bacilli which appear very small and fine except when their capsules are stained. They grow very rapidly on ordinary mediums and produce a mucoid, sticky growth.

Whether there is a characteristic, pathologic lesion produced by this group, which can be distinguished from a pneumococcus lesion, can be decided only by more complete study of our material.

The second point we wish to make is that these organisms should not be mistaken for influenza bacilli. If the findings in smears and sections are checked by cultures, preferably on plain agar, there is little chance of error; but if smears, for example, of sputum or washings of peritoneal exudate of a mouse, are examined only by microscope, mistakes might easily occur. The organisms of this group are much smaller and finer than one might suppose from the character of the growth, and they resemble the influenza bacillus quite closely in most preparations. The same is true of sections.

EPIDIDYMITIS AS A COMPLICATION OF MENINGITIS

A STUDY OF TWENTY-FOUR CASES*

JOSEPH R. LATHAM, M.D. (Belhaven, N. C.)
First Lieutenant, M. C., U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

As a feature of meningococcus sepsis, epididymitis has heretofore been little noted. At Camp Jackson, however, during the epidemics of the past year, it has assumed decidedly an important place in the list of complications of meningitis. In one series of 290 cases, it occurred in more than 3 per cent. During a sporadic outbreak occurring during October, 1918, it has been much more frequent. In this series of thirty-six cases, more than a third of the patients developed epididymitis as a complication during their convalescence. So frequently has it occurred, and so typical is its onset and its course, that it is with us beginning to assume almost the dignity of a symptom rather than of a complication.

So far as we have been able to determine clinically, it is an epididymitis without definite orchitic involvement. Certainly if the latter occurs at all, it is only slight and transient. The picture is that of a hard, sharply demarcated epididymis, with the globus major as the primary focus in practically all of the cases. The process quickly extends to the body of the epididymis. The tunica vaginalis testis usually contains a little fluid, its presence being proved by transillumination.

The cause of the complication is still in doubt. Our cases of meningitis are all in men between 20 and 30; that is, at the age of greatest sexual activity. All are treated by massive intravenous doses of antimeningococcus serum. Inquiries, however, in regard to its incidence in cases of pneumonia treated by serum in virtually the same way, are negative; it does not occur. The nature of the lesion; its localization in the epididymis, would certainly point toward its being septicemic in its origin. Our records show as a matter of fact that 70 per cent. of the cases had a positive blood culture; 20 per cent. showed a negative blood as well as a negative spinal fluid. The other 10 per cent. showed the meningococcus present in the spine; that is, the organism had reached the stage of localization and was no longer a systemic invader.

From these statistics one would expect that the onset of an epididymitis would be a danger signal. As a matter of fact, it is not. There has been no case of relapse following this complication. Furthermore, there is no relation between the severity of the clinical features of meningitis or of sepsis, and the occurrence of epididymitis as a complication. Some of the mildest cases of meningitis show most marked epididymal involvement.

Apparently venereal diseases are not factors in the causation of this complication. Venereal history was elicited in 32 per cent. of the cases. Certainly none of this series of twenty-four had active gonorrhea. It seems, in passing, reasonable to assume that the meningococcus, being so close a relative to the diplococcus of Neisser, may have also a localizing affinity for the epididymis.

---

* From the Medical Service of the Base Hospital.

The accompanying table outlines cases taken at random from our series. As will be noted, every case in which the meningococcus was found and typed showed a Type IV meningococcus. Although we have had several cases of parameningococcus infection in our series, none of them have shown epididymitis as a complication. It is interesting to note that the Type IV meningococcus is biologically and culturally the nearest relative to the gonococcus.

The morbid anatomy of the condition is not known. No case in which it occurred has gone to necropsy. Neither has any case shown any evidences of pus formation. Puncture smears taken in four cases failed to show the presence of meningococcus. Cultures made at the same time remained sterile.

The lesion begins as a discrete, brawny induration of the globus major of the epididymis. Usually the involvement is unilateral. In 10 per cent. of our cases, it was bilateral. The inflammation very quickly extends to include the whole epididymis. There is some heat and redness, which quickly subsides. In the majority of cases there is a small hydrocele, which serves to make one think that the testicle itself is larger than normal.

The epididymis is quite tender to palpation, the upper pole being the seat of great tenderness. The testicular body is not particularly tender. There is practically no febrile rise associated with its onset; if it occurs, it lasts only a few hours and is very slight.

There is very little pain associated with the complication. As long as the patient remains still, he is comfortable. When he moves, he usually does so very gingerly. After the second day, or at most, after three days, even this slight discomfort disappears, and convalescence progresses apparently without halt.

The diagnosis is usually self evident. The very marked increase in size of one or both testicles, associated with so little pain and febrile reaction, is a very striking feature. There is none of the exquisite tenderness and pain of a mumps orchitis. Probably this is due to absence of any distinct testicular involvement. The lack of constitutional disturbance may readily cause the complication to be overlooked, especially if the patient is toxic, or the swelling and induration slight.

Its differential diagnosis has largely been given above. A few cardinal points present themselves:

1. The striking preference which the complication shows for the epididymis and especially the globus major.
2. The absence of any demonstrable venereal infection.
3. The slight pain and discomfort, and the absence of constitutional disturbance.
4. Its occurrence during the course of a meningococcus infection and especially during convalescence.
5. The lack of atrophy and the gradual return to normal of the testicle and epididymis involved, this differing most decidedly from other conditions such as mumps and the chronic infections of syphilis and tuberculosis.

OBSERVATIONS IN TEN CASES

Patient	Fever During Complication	Laboratory Data			Clinical Features on Which Diagnosis Was Made	Part Affected	Result
		Blood Culture	Spinal Fluid	White Blood Cells			
1	None	Type IV meningococcus	Type IV meningococcus	21,700	Stiff neck; hyperesthesia; Kernig; Brudzinski; fading rash	Globus major principally; both epididymides	Rapid subsidence of inflammation; no atrophy
2	None	Negative	Type IV meningococcus	......	Back and neck stiffness extreme; Kernig; Brudzinski very pronounced	Right epididymis....	Rapid subsidence of inflammation; globus major remained hard and discrete
3	None	No organisms	No organisms	23,200	Delirium; hyperesthesia; petechiae; stiff neck; Kernig	Both epididymides	Complete subsidence; no enlargement of epididymis remaining; no atrophy
4	None	Type IV meningococcus	Type IV meningococcus	35,400	Marked headache; marked neck stiffness; Kernig	Right epididymis; globus minor most involved	Globus minor remained hard and discrete; not tender; no atrophy
5	100.2 F., one day	....	Meningococcus, not typed	21,400	Macular and petechial rashes; delirium; extreme neck stiffness; Kernig	Both epididymides on left side; globus minor most involved	Inflammation subsiding; still a little tender to palpation
6	None	Meningococcus, not typed	Type IV meningococcus	......	Petechiopurpuric rash; stiff neck; Kernig; leg Brudzinski; external rectus palsy	Right epididymis....	No remaining inflammation; still slight enlargement of epididymis
7	99.6 F., one day	Type IV meningococcus	Type IV meningococcus	31,000	Petechiae; delirium and hyperesthesia; neck stiffness; Kernig; leg Brudzinski	Right epididymis....	Rapid subsidence; no remaining enlargement
8	None	Meningococcus, not typed	No organisms	37,800	Delirium; stiff neck; Kernig; Brudzinski; ill balanced reflexes	Right epididymis....	Globus major remained hard; discrete but not tender; no signs of atrophy
9	None	No organisms	No organisms	28,000	General hyperesthesia; chill, fever, vomiting; petechial rash	Right epididymis....	Rapid return to normal; no atrophy
10	99.6 F., followed by two days' fever	No organisms	Type IV meningococcus	16,400	Profuse petechial rash; general hyperesthesia; stiff neck; Kernig	Left epididymis.....	Rapid return to normal; no atrophy

A routine study of the urine in these cases fails to show any evidence of concurrent renal or bladder involvement. This is not to be wondered at, since the meningococcus very rarely shows a localizing affinity for the renal parenchyma. Blood counts taken at the crest of the epididymal inflammation showed a moderate leukocytosis. This finding is of course subject to question because of the well known high leukocyte count of uncomplicated meningitis.

Prognosis in these cases is very good. As stated above, there has been no case of death in the entire series. In those cases under observation there has been no evidence of testicular atrophy. The epididymis manifests a slow but progressive tendency to return to its normal size and consistency. In the cases observed, this change covered a period of from six weeks to three months. The globus major may remain slightly enlarged for an indefinite period. Its occurrence means nothing as a warning of relapse. Blood cultures taken during the acute stage are uniformly negative.

Treatment consists principally in leaving the patient alone. He is ordered to remain on his back and encouraged to drink plenty of water, and his emunctories are kept working at capacity. If the dragging pain is an annoying feature, the use of a towel spread between the legs or of a small pillow placed so as to support the scrotum will be found sufficient. The patient as a rule discards a suspensory very promptly if one is given him. Aside from these foregoing measures, nothing is done.

SUMMARY OF FEATURES

Attention may be called to:

1. The lack of relation between occurrence of epididymitis as a complication, and the severity of the meningococcus infection.
2. The lack of relation between the physical signs and the objective and subjective symptoms.
3. The absence of any associated orchitis.
4. The uniformity with which the complication attacks the epididymis, especially the globus major of the epididymis.
5. The comparatively quick return to normal and the absence of any tendency to atrophy, either primary or secondary.

EXPERIMENTAL MEASLES

A REVIEW *

LUDVIG HEKTOEN, M.D.
CHICAGO

In view of the increasing interest in the study of measles and its complications, it may be of advantage to survey briefly the results of the efforts to produce measles experimentally. The experiments in question fall in two groups, those on human beings and those on animals, especially monkeys.

EXPERIMENTAL MEASLES IN MAN

So far as known, the first attempt to inoculate man with measles was made by Francis Home in Edinburgh in 1758. The suggestions probably came from Alexander Monroe the Second, and the purpose was not to study the nature and seat of the virus but to insure the disease "in a gentle and favorable degree" in the hope that many might "be preserved from that malignant sort which often proves mortal, and is always dangerous." Home[1] ordered a very superficial incision to be made "amongst the thickest of the measles, and the blood which came slowly away was received on some cotton." He then made an incision in each arm of the person to be inoculated, let the wounds "bleed for a quarter of an hour before the cotton was put in, that the fresh blood might not wash off, or too much dilute the morbillious matter." The cotton remained three days in the wounds.

Home inoculated fifteen children and concluded that in most instances measles developed in mild and modified form. However, there are good grounds to doubt Home's conclusion: His records show that in no case was the time between the inoculation and the supposed measles rash, which is not described in detail, more than ten days; his Case 10, which he describes as a typical measles from inoculation, "took measles again" a few weeks later; and in the event any of the fifteen children did have measles as claimed by Home, nothing is said as to what steps if any he took to exclude spontaneous infection.[2]

Besides Home, Wachsel,[3] Speranza,[4], von Katona,[5] McGirr,[6] Bufalini[7] and others[2] claim that they have inoculated human beings with measles; but in many cases the nature of the resulting disease, sometimes very mild, is not clear, and in practically all the possibility of natural infection does not seem to have been excluded.

Although Mayr[8] has given but few details about his experiments, his results seem to be accepted as trustworthy. He produced measles in six instances by the introduction into the skin of the material obtained from scratching the center of a rubeolous spot; and on placing fresh nasal secretion of early measles on the nasal mucosa, measles appeared in regular time in two of three experiments, the eruption coming out on the fourteenth day. In these cases the disease was typical though mild, and the patients are said to have remained free from subsequent attacks.

In my own experiments,[2] very special care was taken to exclude natural infection. In the first experiment, 3 c.c. of blood from a measles patient on the first day of the rash were mixed with 50 c.c. of ascites broth, and after an incubation of twenty-four hours at 37 C., 4 c.c. of this mixture were injected subcutaneously. In the second experiment, 2.5 c.c. of blood from a measles patient, taken about thirty hours after the first appearance of the rash, were mixed with 75 c.c. of ascites broth, and after an incubation of twenty-four hours at 37 C., 5 c.c. of this mixture were injected subcutaneously. In both cases the inoculated broth remained perfectly sterile, the cultures being kept under aerobic conditions. In the first experiment the temperature rose on the thirteenth day, and on the next day a typical measles rash appeared. In this case there were no respiratory symptoms at all. In the second experiment the temperature went up on the eleventh day, a mild conjunctivitis developed with a little cough and redness with increased secretion in the throat, and on the fourteenth day a typical rash came out. There was prompt recovery in both cases.

These experiments have been accepted as showing that the virus of measles is present in the blood in measles sometime at least during the first thirty hours of the rash. It is true that a doubt has been raised[9] as to the first case because there were no catarrhal symptoms; the rash was typical, however, and it is believed that naturally measles may occur without such symptoms (morbilli sine catarrho).

The most recent effort to immunize against measles by inducing a mild form of infection is that by Herrman.[10] In forty infants less than 5 months of age he gently rubbed the nasal mucous membrane with swabs

on which had been collected the nasal mucus of measles patients twenty-four hours before eruption; fifteen gave a rise of temperature between the eighth and fourteenth days, and in a few instances a small number of indistinct spots were noted on the face and body between the fourteenth and eighteenth days. When more than a year old, four of these children came in intimate contact with patients with measles without becoming sick, and at the ages of 21 and 23 months two others were reinoculated without producing measles. The experiment is perhaps not to be regarded as completed because proof of immunity is not yet established.

Instances of apparent accidental inoculation of measles seem to be very rare. The case described by Michael[11] of supposed accidental inoculation with involvement especially of the inoculated arm is of doubtful nature as it may have concerned a lymphangitis.

EXPERIMENTAL MEASLES IN ANIMALS

Older veterinary writers described what they thought was measles in domestic animals, especially sheep and swine; but it is now established that it concerned other diseases.[12]

In the case of the dog brought to the notice of Chisolm[13] as an instance of measles, there is no record of any rash.

An ingenious hypothesis that mice may be a source of measles has been advanced by King,[14] but we have no experimental evidence indicating that the virus can survive and increase in this animal.

Going over the efforts to inoculate animals with measles, we find that negative results are reported by Warschawsky,[15] who injected small pigs and rabbits with blood taken in the eruptive stage, and by Pomjalowsky,[16] who injected measles blood into guinea-pigs, rabbits and small pigs.

Behla[17] placed warm nasal mucus and saliva from measles patients on the nasal and oral mucous membrane of rabbits, guinea-pigs, cats, mice, dogs and lambs, but without any positive results except for rather indefinite catarrhal symptoms. He then made a similar inoculation in a pig, 6 weeks old, after first scratching the mucous membrane with a sharp needle; on the fourth day the animal became sick with running at the nose and eyes, and on the eighth day a rash began to appear which soon spread over the whole body, and which Behla regarded as a true measles rash, especially because in a few days scaling took place. During this eruptive period, so-called protozoal bodies were present in the blood and in the secretions of the eye, nose and throat. Two large hogs also became infected presumably, so Behla concluded, from contact with the inoculated pig.

Repeating Behla's experiments, Josias[18] rubbed measles secretions over the throat, nose and eyes of several young pigs, but without any effects. He suggests that Behla may have encountered an eruptive disease natural to swine.

Geissler's[12] experiments gave only negative results. He used white sheep, swine, goats, dogs and cats, which were inoculated in various ways: Throat and nose secretions from the initial and eruptive stages of measles were smeared while still warm on the eye, nose and throat of the animals; measles secretions diluted with salt solution were sprayed into the throat; in some cases nasal mucus and crusts were rubbed into small wounds in the ears; in one sheep, fresh scales were placed in a pocket in the skin; and scales were rubbed on fresh erosions. The only changes produced were local. In the animals inoculated in the nose and throat, catarrhal phenomena were observed, but no rash.

Jurgelunas[19] inoculated blood from patients in the eruptive stage of measles into suckling pigs and rabbits, but without effect.

The animals so far mentioned do not seem to be susceptible to measles; at any rate, no one has succeeded in reproducing measles in any of them except possibly Behla in the pig; but his claim to that effect is so far without any support. It now remains to review the experiments on monkeys.

Chavigny[20] describes what he regards as a typical attack of measles in a monkey (cyanocephalus from Zanzibar) 3¼ years old, whose keeper had measles. Eight days after the keeper fell sick the monkey developed oculonasal catarrh, a mild bronchitis, and some fever; six days later a typical measles eruption appeared on the face, and then on the trunk and limbs, becoming confluent, especially on the abdomen.[21] Recovery was gradual with a furfuraceous desquamation lasting a few days. Another monkey (cercopithecus) exposed in the same way remained well.

Apparently Josias[18] was the first to try to inoculate monkeys with measles. He took the catarrhal secretion in the early eruptive period, the first or second day, and rubbed it over the lining of the nose and throat, injecting in some cases also from 0.5 to 1 c.c. of measles blood subcutaneously. In five rhesus monkeys no reaction resulted, but in three monkeys ("sajou") an eruptive fever developed "having all the symptomatology and the duration of measles." In one case the reaction developed thirty-two days after the monkey was placed in a measles ward and twenty-seven days after swabbing the nasal and oropharyngeal membranes with measles secretion, the animal in the meantime remaining in the ward and hence being exposed to direct contact; the eruption, a lenticular, macular erythema of the face and limbs, lasted about five days, and there was a slight furfuraceous desquamation; the rectal temperature in this period ranged from 39.4 to 41 C. (102.9 to 105.8 F.), and there was a persistent diarrhea. In the other two monkeys ("sajou robustus") the reaction was less severe; in one it came on thirteen days after the introduction of measles secretion, and small, red, poorly defined spots appeared on the face, which faded in a day or two; in the other, which received measles blood also, fever, coryza, and erythema of the face, neck and abdomen developed. To Josias it seemed as if the rhesus monkey was refractory to measles, whereas the "sajou," and especially the "capucin" variety, was susceptible. A rhesus ("guenon macaque"), which lived in a measles ward for six months and played constantly with the children did not fall sick.

Grunbaum[22] injected a chimpanzee with measles blood and clothed it in a measles nightgown, without any effect. His record of an experiment on another chimpanzee is as follows:

> May 22, clothed in nightgown from case of measles. No effect.
>
> June 5, swab from case of measles applied to nose and throat: Temperature, 100.2 F.
>
> June 7, coryza. Temperature, 99.6 F.
>
> June 11, slight roseola. Temperature, 102 F.
>
> June 15, rash gone. Temperature, 99.2 F.
>
> It remains doubtful whether this animal was really infected with measles. Coryza is not uncommon in the chimpanzee, although here it seemed to have a causal relation to infection.

We come now to the most important work on measles in animals, namely, that by Anderson and Goldberger.[23] These investigators produced measles in the monkey (*Macacus rhesus, cynomolgus* and *sinicus*) by the injection of blood and of nose and throat secretions of measles patients. In the case of blood, several methods of injection were used, but intravenous injections (by the external saphenous vein) came to be preferred, the amount injected varying from 2 to 5 c.c. Fresh, defibrinated blood was used most, but positive results were obtained with serum as well as with the washed corpuscles. The best results were secured with blood drawn just before or during the twenty-four hours immediately after the appearance of rash; with blood drawn later the results were more uncertain, and by about seventy-two hours after the onset of the rash the infective power seemed wholly lost. Mixed buccal and nasal secretions, diluted with salt solution and injected subcutaneously, also proved infective, but not always, being most infective early in the attack. Experiments with scales did not succeed.

No doubt a limited range of infectivity of measles blood and secretions, coupled with a variable susceptibility in the monkey, will account for many of the failures to inoculate this animal with measles.

According to Anderson and Goldberger, monkeys, when successfully inoculated, after a variable period, usually from six to ten days, develop a moderate fever, lasting from four to five days, and frequently also a more or less well marked eruption, which begins on the third day or so of the fever. Sometimes respiratory symptoms—cough, coryza, etc.—also appear. The eruption usually comes out first on the chest and abdomen, later on the thighs, arms and face, and it may then be fading where first seen. The typical eruption consists of small, red, rose-tinted or coppery maculopapular spots, which may coalesce into larger patches; on fading, stained spots may remain and a branny scaling may take place. "Some of our animals have presented as typical a picture of measles as will be seen in a well-marked case of the disease in human beings" (Anderson and Goldberger). Monkeys that passed through febrile reactions of this general character did not react to second injections of virulent measles blood; and the blood of monkeys in the midst of a reaction (not necessarily associated with eruption) would transmit the disease to other monkeys. Indeed, Anderson and Goldberger in this way passed the virus in one case through six successive monkey groups and again through three, but without any appreciable change in its virulence. They were able also to transmit the disease by contact through confinement of well with infected monkeys in the same cage. Here may be mentioned also their results from especial tests of measles virus in blood: They found that the virus is filtrable, that is, the serum of measles blood diluted with salt solution and filtered through a Berkefeld candle (size not given) remained virulent; drying blood for twenty-five and one-half hours or freezing for twenty-five hours did not destroy the virus, and some infective powers seemed to be retained by blood kept at 15 C. for twenty-four hours; heating for fifteen minutes at 55 C. destroyed the virus. Anderson and Goldberger always found that infective measles blood, monkey or human, caused no recognizable growth in glucose broth in fermentation tubes.

The results of Anderson and Goldberger are confirmed by Nicolle and Conseil,[24] Hektoen and Eggers,[25] and Lucas and Prizer.[26] Nicolle and Conseil injected measles blood drawn twenty-four hours before the eruption into the peritoneal cavity of a bonnet monkey (*Macacus sinicus*). Nine days later the monkey developed a fever, which on the second and third days reached 40 C. and which continued for six days. No eruption was observed. In rhesus monkeys injected with citrated measles blood, Hektoen and Eggers observed in addition to mild febrile reactions, accompanied in one case with a sparse maculopapular rash, also a leukopenia, principally neutrophilic and corresponding in point of time to the leukopenia of human measles. Leukopenia occurred also in a monkey injected with the blood of another monkey taken at the time of its reaction to human measles blood. Monkeys injected with human blood from other sources than measles patients did not develop any such leukopenia.

In two monkeys injected with measles serum and measles serum and corpuscles, respectively, Lucas and Prizer observed not only a measles leukopenia, typical even in details, but also Koplik spots in considerable numbers on the tenth day. There was no characteristic skin eruption, only a transient erythema of the face and forehead. On the ninth day, blood from these animals was injected into two other monkeys, and in one Koplik spots appeared on the tenth day. They point out that the occurrence of the leukopenia and of Koplik spots leaves no doubt as to the successful transmission of the disease.

Jurgelunas[16] injected measles blood subcutaneously and intravenously into monkeys; he brought monkeys in contact with measles patients, and he rubbed measles mucus on the healthy as well as scarified lining of the mouth and pharynx of monkeys; but all remained well except one ("Pavian"), injected intravenously with 5 c.c. of defibrinated blood drawn the day before eruption. On the tenth day this animal was sick, the pharynx was red, and there were some small red spots on the face, abdomen and thighs, but there was no fever; death took place on the twelfth day, and the organs were found to be sterile. The eruption did not clearly resemble that of measles, and Jurgelunas regards this experiment as having given a doubtful result.

Marzinowsky[16] experimented without result on one rhesus monkey.[27]

SUMMARY

We may conclude from the results of human experiments that the cause of measles is present in the nasal secretions, scrapings of the skin (epithelial debris and blood), and the blood, during the earlier part of the eruptive stage. Attempts to produce by inoculation a mild, modified or localized form of measles have not yet given conclusive results.

The only animal proved susceptible to measles so far is the monkey, but the susceptibility is not marked and seems subject to variation. The disease in the monkey is mild and takes the form after an incubation of several days of a brief fever, with which may be associated more or less typical skin changes, respiratory symptoms, Koplik spots, and the characteristic measles leukopenia. The results in monkeys show that the cause of measles is present in the nasopharyngeal secretions and the blood at least twenty-four hours before the rash, as well as for a day or two afterward.

CHANCRE OF THE FINGERS

DOUGLASS W. MONTGOMERY, M.D.
AND
GEORGE D. CULVER, M.D.
SAN FRANCISCO

Physicians, especially gynecologists and obstetricians, are particularly liable to syphilitic infection of the fingers. Nurses, one would think, are in almost the same danger in their professional work; but in them we have seen fewer instances of this unfortunate accident. Case 1 is a typical and instructive instance:

CHANCRE OF THE FINGERS SIMULATING PARONYCHIA

Case 1.—June 19, 1913, a professional nurse was referred to us for a continuance of her treatment. Toward the end of the previous February she acquired what appeared to be a pyogenic infection under the edge of the right thumb nail. Shortly afterward a similar infection showed itself under the free edge of the nail of the left index finger, presumably following a wound with a safety pin. Both nails were evulsed, May 7. In both, therefore, the suppurative process had lasted considerably *more than* two months. A characteristic papular eruption, and mucous patches in the mouth, appeared, May 26. When we first saw the patient, June 19, there was just an indication of a *fading* roseola of the palms. No other mode of entrance of the syphilitic virus than by the fingers could be ascertained by either the physician in charge of the case or by the nurse herself. The paronychias were particularly slow in healing, and the syphilitic eruption appeared at a time corresponding to the appearance of the paronychias as primary sores. That there should be two paronychias, both of which were probably chancres, was interesting and rare.

A paronychia-like chancre is peculiarly difficult to recognize, as it does not in any way resemble an initial lesion. The nail and the nail fold completely obliterate all its characteristics. An obstinate, long enduring and exceedingly painful panaritium, occurring in a physician or nurse, should excite our suspicions, and should lead to repeated examinations for spirochetes. After five weeks the blood might be examined for the Wassermann reaction. An indolent bubo at the epitrochlea or in the axilla has a diagnostic value. Any suppurative lesion of the finger, however, might give rise to such a swelling.

CHANCRE ON THE WEB OF THE FINGERS

Any sore lasting longer than an ordinary infection and situated on the dorsal surface of the web between the thumb and the index finger, or on that between the index and the middle finger in a gynecologist or an obstetrician, should give rise to the gravest suspicion of its syphilitic nature. These two localities come against the entrance of the vagina during examinations, and the skin is put on the stretch, so that any wound accidentally there is apt to be opened to its utmost, allowing an easy entrance for the virus from syphilitic lesions of the vulva or vagina. Case 2 is an excellent example of this kind of accident:

Case 2.—A physician, aged 47, consulted us, March 23, 1909, for a sore that had appeared on the back of the web between the left thumb and index finger four weeks previously. He said that it had appeared as a bleb. There was now present an ulcer with a gray floor and soft, heavily infiltrated, blue base. The patient noticed swelling of the lymphatic nodule in the left axilla four or five days after the appearance of the lesion. There was no swelling at any time of the epitrochlear lymphatic gland. Two weeks after the appearance of the sore, there manifested itself on the abdomen a bright, evenly distributed rash, like that of scarlatina, which vanished in a day or two. In still another week the patient suffered from chills and fever. The eruption for which he consulted us had appeared two weeks previously. There was present, when we saw him, a deep red papular syphilid with much infiltration, scattered over the trunk, and to a less extent on the limbs. The only lymphatic enlargements demonstrable were in the left axilla and in the groins. His temperature was 99 F. in the morning and from 100.5 to 101 in the evening, and was associated with chills without a distinct rigor. Two small faintly stained spirochetes were found in a smear from the initial lesion. None were found in smears from a papule on the arm.

In this history the time given for the appearance of the chancre was undoubtedly incorrect. It was too close to the appearance of the eruption.

One must not allow absence of enlargement of the epitrochlear lymphatic nodule to influence one unduly in arriving at a negative conclusion in chancre of the hand, as some of its lymphatic vessels pass through the nodules of the epitrochlear region, while others go direct by to the axilla. Therefore, if the chancre is in a district drained by vessels that pass directly to the axilla, the nodules at the elbow may not be swollen or indurated.

I do not know anything about the subsequent history of this case, and it dates back to the time previous to the introduction of arsphenamin and to the notable improvements in the treatment of early syphilis. Nevertheless, we now know that it would have been of inestimable advantage if the patient could have had treatment before the cutaneous eruption appeared.

---

[27] A. F. Hess (German Measles (Rubella): An Experimental Study, Arch. Int. Med. **13**:913 [June] 1914) inoculated a rhesus monkey intraperitoneally with 3.8 c.c. of blood from patients with rubella, but the results were negative.

CHANCRE OF THE FINGER

A chancre, no matter in what situation, usually ulcerates, but it does not do so necessarily, and Case 3 is an instance in which it constituted simply an extensive infiltration:

Case 3.—Feb. 25, 1910, a physician consulted us for an eruption which he first had noticed about four weeks previously. The eruption was a characteristic papular syphilid, not itchy, and appeared to come out suddenly on the forehead, back and chest, and scatter down sparsely over the arms. There were a few thinned out areas in the hair of the scalp posteriorly, and there was a mucous patch on the right tonsil. Four days before the appearance of the eruption the patient had a characteristic, intense, occipital headache.

Before the previous Christmas, he had noticed a painless induration, without break of the surface, situated on the radial side of the second phalanx of the left index finger. This he cut open. There was adenopathy in the left axilla, but none of the left epitrochlea, and a very small one of the right, so that the marked lymphatic enlargement in the glands, receiving the drainage from the affected district, so valuable in hunting for the seat of extragenital chancre, was of very little aid here. The dusky induration appearing before the eruption admitted, however, of no doubt as to its being the primary lesion. There was still another peculiarity, which sometimes occurs in the primary sore, an extraordinarily long enduring dusky redness. This was noted as being still present, Aug. 2, 1912, twenty months after the inception of the chancre.

As regards the acquisition of the disease, the doctor had operated on syphilitic tonsils in a Japanese, the middle of the previous November, and, as before mentioned, the induration on the finger was noticed before Christmas.

If for no other reason than to keep one on the alert in diagnosis, the subject of the primary lesion of syphilis, as it occurs extragenitally, is well worth considering. This is especially true nowadays when the results of early treatment, necessarily dependent on early recognition, are so brilliant, and the consequences of failure to recognize this disease are now known even to the laity as being so portentous. The physician, therefore, in recognizing the true nature of the disease may make a brilliant hit, or in failing to do so may achieve a failure, which from its very nature as appertaining to an eminently chronic malady may continue a reproach during his entire life of practice.

The essential difficulty, however, of recognizing these lesions in these situations in their early stages is shown by the cases cited, for one instance occurred in a professional nurse working with a physician, and the other two were in physicians in active practice; yet in no case was the true nature of the disease suspected until the appearance of the eruption.

323 Geary Street.

War Training as a Postgraduate Course.—No postgraduate course can equal the actual benefits to the professional man, no clinic can complete a system of organization so thoroughly as the war training is going to show the way. It will teach a system of efficiency to the medical man that will be a great asset to him after returning to private life. This is surely worth the while. Incidentally, it will teach the people the significance of the medical profession and the rôle it fills in regard to health. It will teach the people, as the insurance companies already know, the benefit of a thorough physical examination in both health and disease, especially in health.—President's Address, Minnesota State Medical Society, 1918.

A PULSE RATE STANDARD FOR RECRUITS *

THOMAS ADDIS, M.D. (San Francisco)
Captain, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

During routine work on the cardiovascular board at Camp Lewis, many recruits were seen who complained of symptoms suggestive of circulatory disorder, although no indication of any cardiovascular defect was obtained by the methods of inspection, palpation, percussion or auscultation. In this group of cases a functional test might be expected to help in the determination of the existence and of the grade of true circulatory disability. The regulations as to the examinations of recruits provide such a test. It is based on the changes in pulse rate induced by alteration in the position of the body and by exercise. The pulse rate is taken with the subject standing. He is then directed to lie down and the rate is again counted; thereafter he hops 100 times on the left foot, and the pulse rate is counted immediately and two minutes after this exercise with the recruit in the recumbent position.

The impression, however, of those who had had most experience with this test was that no importance could safely be attached to the results obtained by it unless they showed an extreme degree of acceleration of the pulse rate on exercise and a marked delay in the return to the pre-exercise level. The great majority, therefore, of men with symptoms but without signs of circulatory disability were accepted for full military duty, though often with doubt and hesitation.

This state of uncertainty in regard to the interpretation of the results of the regulation exercise test was all the more to be regretted since Mackenzie, Lewis and others who have had a large experience in the classification of soldiers with predominantly subjective cardiac disorders have found the pulse rate reactions to the strain of physical exertion one of the most valuable of all the objective criterions that they used as aids in the disposition of such cases.

It seemed not unlikely that the difference between their opinion and ours might arise from our want of exact knowledge as to what was a normal and what an abnormal reaction to the strain of the test we used. It was with the object of obtaining this knowledge that the work here reported was begun.

METHOD USED IN DETERMINING THE LIMITS OF NORMAL VARIATION IN PULSE RATE

The limits of normal variation can be deduced from a sufficient number of observations on normal individuals by the application of statistical methods. The measure of variation here used is known as the "standard deviation." It is obtained by finding the square root of the mean of the squared deviations from the arithmetical mean of the observations. This method is the one most commonly used by statisticians and biologists for such a purpose as ours.

The usefulness of a normal standard obtained by this or any other method will largely depend on the extent to which the conditions in the group of normal individuals on whose reactions it is founded are comparable with the conditions surrounding the individuals to whom the standard is to be applied. The men for whom the standard was needed were newly arrived recruits, and "normals" were accordingly chosen from this clas sof men. They were questioned in an indirect manner as to the absence or presence of dyspnea on moderate exertion, and those in whom this symptom was absent were chosen for observation. Though this is a crude method of selection, it at least excludes the recruits with cardiac symptoms for whom the standard was especially required. The tests were made in the men's barracks between 6 and 9 p. m.

---

* From the Cardiovascular Board, Camp Lewis, Wash.

A CRITICISM OF THE MANNER IN WHICH THE REGULATION EXERCISE TEST IS COMMONLY CARRIED OUT

It was obviously desirable that the exact technic of the regulation exercise test as used by local and cardiovascular boards should be followed in establishing the standard, not only because it is the authorized test and accordingly in general use, but also because of its convenience and simplicity. It requires no apparatus, no furniture beyond a table, is immediately applicable under all circumstances, is rapidly carried out, and gives a numerical value to the reaction to four changing degrees of strain. But before making any very extensive series of records, it was thought advisable to make a preliminary analysis on a relatively small number of observations. It was thought that some idea might thus be obtained as to how many normals would have to be examined in order to obtain a standard that would be of value in dealing with individual cases.

For this purpose a physiologic principle of very general application was employed as a measure of the adequacy of the data. Under the stimulus of a demand for increased work or output, the organs of the body respond with an increase in function beyond the degree of functional activity existing at the time the demand arises. With a constant stimulus the relative extent of this increase in function will depend on the level of activity of function at the time of application of the stimulus. If the stimulus comes at a time when the organ is already working near to its total capacity, the percentage of increase in function is less than that which would have been induced if the stimulus had been applied at a time when the organ was working at a subnormal level. If the heart is already beating rapidly when the regulation test is started, the percentage of increase over the initial rate will be less than if the stimulus of change of position and of hopping had fallen at a time when the heart was beating slowly. If, therefore, a series of observations on normal individuals is arranged in groups according to the lowest pulse rates, which are those taken in the recumbent position, and the average percentage increase over this basal rate of the counts made while standing, after hopping, and two minutes after hopping is found for each group and plotted as points on a chart in which the average recumbent pulse rates of the different groups is the abscissa, it will be found that the lines joining these points will form curves which fall as the resting pulse rate increases. If the number of observations is sufficiently large, factors tending to variability will neutralize one another and the curves will be smooth. If the data are insufficient, the lines joining these points will be irregular and angular in proportion to the inadequacy of the data.

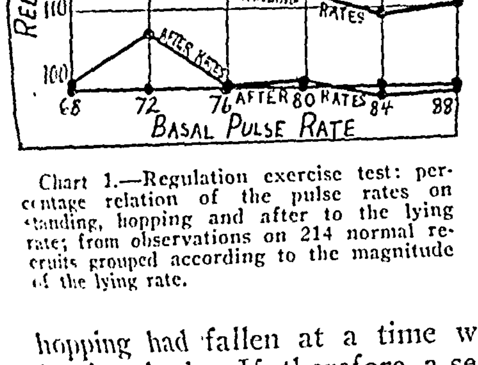

Chart 1.—Regulation exercise test: percentage relation of the pulse rates on standing, hopping and after to the lying rate; from observations on 214 normal recruits grouped according to the magnitude of the lying rate.

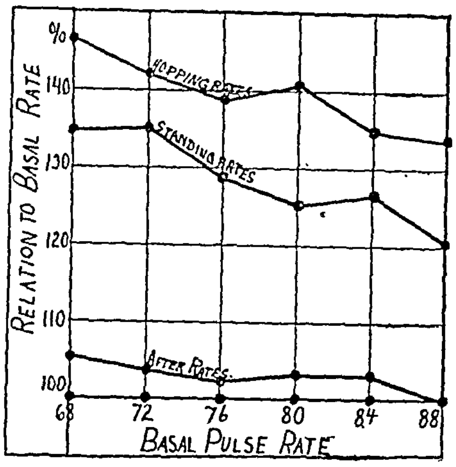

Chart 2.—Modified regulation exercise test: percentage relation of the pulse rates on standing, hopping and after to the lying rate; from observations on 214 normal recruits grouped according to the magnitude of the lying rate.

When 214 normal recruits had completed the regulation exercise test, their records were grouped according to the rates in the recumbent position, that is to say, all the men whose pulse rates while lying down were 72 were placed in one group, those whose lying down rates were 76 in another, and so on. This was the natural system of classification, since the pulse was counted over quarter minute intervals and all rates per minute were thus multiples of four. The rates obtained while standing, immediately afterward and two minutes after hopping were averaged in each group, and each average was expressed as a percentage of the rate in the recumbent position. These percentages for the groups between 68 and 88 are given in Table 1 and Chart 1. The number of cases in groups beyond this range was too small to be reliable.

It is apparent from Chart 1 that there is a considerable degree of irregularity in the curves, though there is a general tendency to a decrease in the percentage relationship as the pulse rate in the recumbent position increases. This irregularity is sufficiently marked to make it appear doubtful whether a standard obtained from normals who manifest such a degree of variability would have much practical value. The normal limits of variation might be so wide as to include all but cases with an extreme acceleration of pulse rate. Therefore, instead of continuing to amass records it seemed advisable to consider whether this variability might not have been exaggerated through

TABLE 1.—RESULTS OF THE REGULATION TEST ON NORMAL RECRUITS ARRANGED IN GROUPS ACCORDING TO THE LYING RATE

No. of Cases in Group	Average Pulse Rates per Minute				Percentage Relation to Lying Rate			
	Lying	Standing	Hopping	Afterward	Lying	Standing	Hopping	Afterward
11	68	79	97	69	100	117	143	101
16	72	87	102	77	100	121	141	107
26	76	86	102	76	100	114	134	100
39	80	90	109	81	100	112	136	101
37	84	92	107	83	100	109	127	99
27	88	97	113	87	100	110	129	99

some removable defect in the manner in which the test was applied.

When the test is judged as above in accordance with the degree of uniformity in the relationship of its different stages to one another, it is apparent that as commonly carried out the regulation test is defective. Any error in the estimation of the lying rate will lead to incorrect classifications and will tend to magnify the variability of the percentage increases produced by change of position and by hopping. It will be remembered that the lying rate is taken immediately after the recruit has changed from the standing to the recumbent position; but in this way the true lying rate is not obtained. It has been found that the rate of decrease in the pulse rate on the person's assuming the recumbent position is subject to considerable variation in different individuals. In some it occurs almost instantaneously, in others, and these comprise the majority, the fall takes place gradually. In most cases, therefore, the lying rate actually recorded represents some stage or other in the descent of the pulse rate from the standing to the lying rate. The originator of the test may have intended that a sufficient period of complete rest in the horizontal position should be allowed before the lying pulse rate was taken; as commonly carried out, however, this precaution is not observed, and the pulse rate observed immediately after lying down is the one that is recorded.

The question may be raised as to whether it is necessary to interpret the results of the test in this manner; for the results at each stage might be taken independently, and the absolute values compared with the limits of the normal for that position or exercise. There seems to be a good reason why this should not be done: The absolute pulse rate at any stage is a resultant of general nervous and metabolic factors from which the part that the cardiovascular mechanism plays cannot be disentangled. But if the resting pulse rate, no matter how many unknown factors enter into its determination, is accurately measured and taken as the foundation of the test, it becomes possible to judge the effect produced by stimuli that call especially for the coordinated activity of this cardiovascular mechanism. Standing and hopping are stimuli of this nature. They are a strain calling for a new adjustment of the heart and blood vessels. One aspect of this adjustment manifests itself in a quickening of the pulse rate over the level that obtains at rest. And it is only this excess over the resting rate that can be taken as an indication of the mode of reaction of the cardiovascular system, not the absolute rates themselves, which are largely influenced by other factors.

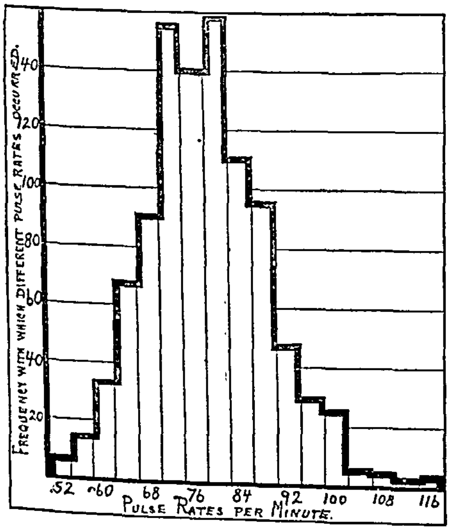

Chart 3.—Frequency distribution of pulse rates observed in the lying position in 1,000 normal recruits.

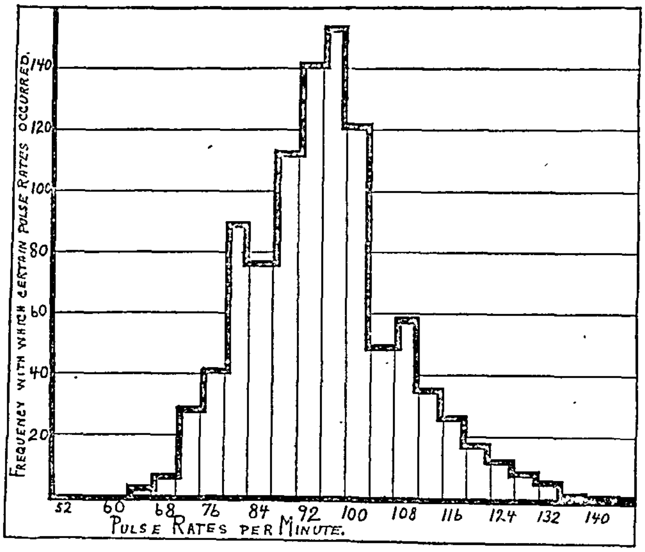

Chart 4.—Frequency distribution of pulse rates observed in 1,000 normal recruits in the standing position.

A MODIFICATION OF THE REGULATION EXERCISE TEST

The only modification required is that the subject should lie quietly on his back for a length of time sufficient to allow the pulse rate to fall to its true resting level. The probability that this modification would be found necessary was apparent before the observations were started; and in order to test the validity of the theoretical considerations on which it is founded, the same 214 normal recruits were directed to lie on their backs for at least fifteen minutes after the pulse rates for the regulation test had been recorded. The pulse rate was then counted as they lay and again immediately after they stood up. The remainder of the test was carried out in exactly the same manner as in the regulation test, the rates immediately and two minutes after 100 hops being recorded.

TABLE 2.—RESULTS OF THE MODIFIED TEST ON NORMAL RECRUITS ARRANGED IN GROUPS ACCORDING TO THE LYING RATE

No. of Cases in Group	Average Pulse Rates per Minute				Percentage Relation to Lying Rate			
	Lying	Standing	Hopping	Afterward	Lying	Standing	Hopping	Afterward
11	68	92	100	72	100	135	146	105
16	72	97	102	75	100	135	142	104
26	76	98	105	78	100	129	139	102

27	88	106	118	88	100	120	135	100

From the figures thus obtained, the percentages of the standing, hopping and after rates to the lying rate were calculated, the numbers in each class being kept for the purpose of comparison the same as in those in Table 1. These percentages are given in Table 2 and Chart 2.

When the curves in Chart 2 are compared with those in Chart 1, it is apparent that they are less irregular, though they are still far from being smooth. This may be taken as indicating a lesser degree of variability in the pulse rate reactions under the conditions of the modified test.

On account of this finding, it was decided to abandon the regulation test, and to determine the limits of variation in pulse rate reactions in normal recruits whose lying rate had been obtained after a period of absolute rest. The disadvantages of this decision were fully recognized. The test as modified ceases to be universally applicable, for in the building in which the board works it is impossible to have any considerable number of men lying down at any one time. The possibility of taking the standing rate as the basis of the test was considered, but it is impossible to standardize any method of standing. The muscular effort put into the act varies with different individuals, and the strain it induces is too variable. The conclusion cannot be avoided that the only way to obtain a true basis for the test is to precede it by a period of complete muscular relaxation.

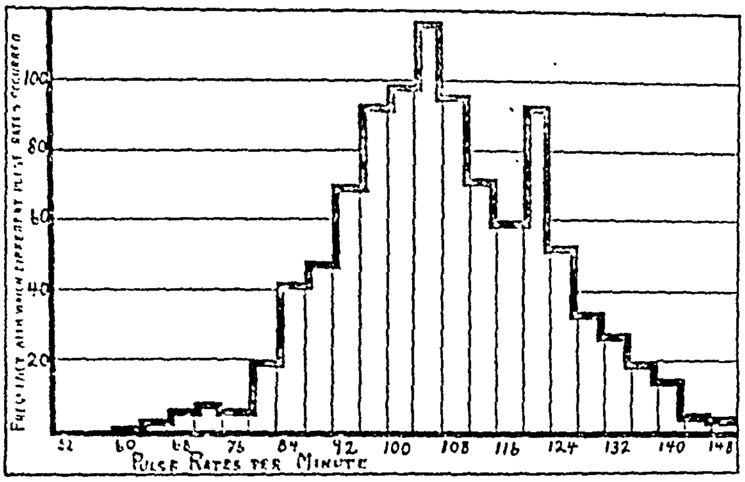

Chart 5.—Frequency distribution of pulse rates observed in 1,000 normal recruits immediately after hopping.

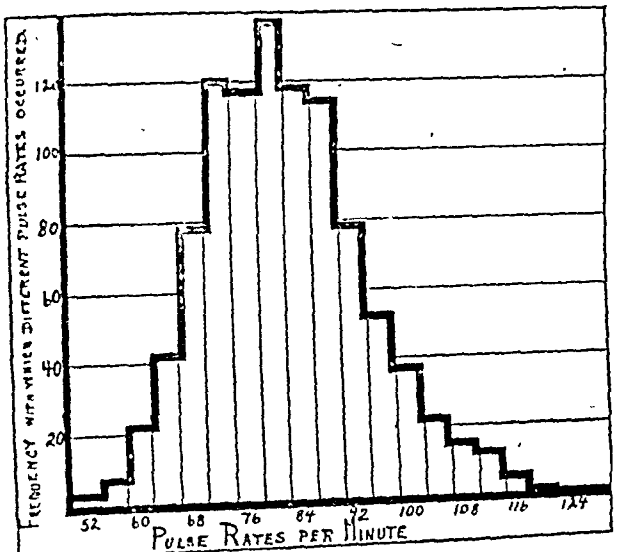

Chart 6.—Frequency distribution of pulse rates observed in 1,000 normal recruits two minutes after hopping.

THE LIMITS OF NORMAL VARIATION IN THE PULSE RATE REACTIONS OF RECRUITS TO THE MODIFIED REGULATION TEST

The pulse rates of 1,000 normal recruits were counted under the conditions of the modified regulation test. The average pulse rate lying down was 78, standing 94, after hopping 107, and two minutes afterward 82. The frequency distributions for each stage of the test in class intervals of 4 pulse beats per minute are given in Charts 3 to 6.[1]

It was shown in the preceding sections that the degree of increase in pulse rate on standing and after exercise is dependent in part on the level of the lying or basal rate. It follows, therefore, that the normal limits of variation are not to be obtained by simply finding the standard deviation of the pulse rates of all the normal recruits. The material must be grouped into classes in accordance with the order of magnitude of the lying pulse rates. Each class must then be averaged and its standard deviation found. When this is done, it will be possible to refer any subsequent record to the particular standard found in normal recruits with the same or approximately the same basal rates as in the record whose normality or abnormality it is desired to determine.

In dividing the data into classes it was thought best to use a class interval of 10 pulse beats in order that the average and standard deviations might be obtained

TABLE 3.—AVERAGE AND STANDARD DEVIATIONS OF THE PULSE RATE REACTIONS OF 1,000 NORMAL RECRUITS

Group	No. of Cases	Lying Av.	Standing Av. σ	Hopping Av. σ	Afterward Av. σ

[1] These charts show indications of errors in pulse counting. In Chart 5, for instance, the curve of descent is broken by a marked increase in the number of pulse rates of 120 per minute. This rate as actually counted was 30 for a quarter of a minute, and the increase at this point is doubtless due to a tendency to record rates of more than 20 or less than 31 as the round number 30.

from larger groups than would have resulted had the natural class interval of 4 been adopted. The averages and standard deviations of these groups are given in Table 3 and Chart 7.

In Chart 7 the averages given in Table 3 are plotted as points on a chart in which the abscissa measures the magnitude of the lying or basal pulse rate averages, and the ordinates the average pulse rates on standing, hopping and after. The limits of normal variation for each group are given by adding each standard deviation to its corresponding average. This gives the upper limit of variation. The lower limit could be obtained by subtracting the standard deviations from the averages, but this limit is of little practical importance since it may be assumed that, in the great majority of cases at least, circulatory disability will lead to an increase and not a decrease beyond the usual pulse rate levels. The sum of the average and the standard deviation is indicated on the chart by a circle, and the lines joining the circles and points represent the standard deviations of the groups. The upper limits of normal variation for the particular basal rates given by the averages of the groups having thus been determined, an approximation to the limits of all basal rates can be obtained by the curves joining these determined limits.

It would appear from the available data that these curves may be straight lines and that the curve for each stage of the test may be regarded as parallel to the others. They have been drawn in this manner in Chart 7, and from them Table 4 has been drawn up which gives the upper limits of the normal of the standing, hopping, and after rates for any observed basal rate.

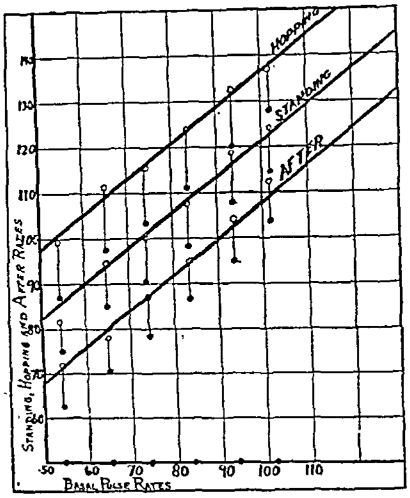

Chart 7.—Limits of normal variation, averages and standard deviations derived from 1,000 observations on normal recruits with the modified regulation exercise test, arranged in groups according to the magnitude of the basal rates. The limits of normal variation are indicated by hollow circles and averages by solid black circles. Standard deviations are shown by the line joining the averages to the limits of normal variation. The curves drawn through the points at which the limits of normal variation have been actually determined give the limits of normal variation in pulse rates on standing, hopping and after for all basal rates.

The following is a detailed account of the method used in obtaining the normal standard, and accordingly of the manner in which the test ought to be carried through with any individual whose record is to be compared with the standard:

1. The recruit lies on his back without moving for fifteen minutes. The pulse rate is then taken. If the rate exceeds 88 per minute he lies still for another fifteen minutes before the pulse is counted.

This is called the basal pulse rate.

2. The recruit rises from bed and stands up. While he is doing so the observer's fingers should be on his wrist, so that he can begin to count the pulse rate as soon as the patient is erect. He counts for fifteen seconds only.

This is called the standing pulse rate.

3. The recruit is then directed to hop 100 times on the left foot at a rate of about two hops to the second. If no one counts for him, he should be told to count the hops himself.

Immediately on the completion of the 100 hops, the recruit lies on his back in bed, and the pulse rate is counted for the first fifteen seconds after he lies down.

This is called the hopping pulse rate.

4. The recruit continues to lie on his back, and exactly two minutes after the completion of the hopping count, the rate is taken again for fifteen seconds.

This is called the after pulse rate.

The counts should begin when the second hand covers one or the other of the five-second divisions of the second hand dial. This may necessitate waiting almost five seconds in some cases, but it is generally more accurate than attempting to gage the position of the second hand between the divisions.

Some find it an advantage to set the minute hand of the watch on an hour division on conpleting the hopping count, in order to make it easier to determine when the two-minute interval has been completed.

Care must be taken to see that the minute hand of the watch does not obscure the reading of the second hand dial.

This standard is in use by the cardiovascular board, but it is too early as yet to form an opinion as to its value. It is also employed as an aid in the grading of cases of neurocirculatory asthenia, and the results are being compared with those obtained by other tests. There is some indication, furthermore, that successive tests carried out on convalescent patients may be of assistance in determining when they should be returned to duty.

When it is found that the pulse rate records of an individual exceed the limits of normal variation at any one or all of the stages of the test, it must be remembered that this simply means that he shows a greater degree of pulse rate acceleration than the great majority of normal recruits. It is not in itself an absolute indication of neurocirculatory disability. It can be of value only in association with other evidence. Indeed, it could hardly be expected that any result of absolute significance as to the effect of strain on the circulatory mechanism is to be obtained from a test in which the only measurement made is that of the pulse rate, for the pulse rate increase on change of position and on exertion is only one factor in a series of complexly interrelated adjustments. But an essential requisite of any test to be used for the purpose we had in view is simplicity and ease of application, and it is doubtful whether anything more exacting than this modification of the regular exercise test would be practicable.

Summary of State Laws on Infantile Blindness.—The reporting of babies' sore eyes to the local health officer or to a physician is compulsory in forty-one states; the reporting law is printed on the birth certificate in ten states; local health officers are authorized and required to secure medical attention for uncared-for cases, or to warn parents of the dangers and advise immediate treatment in twenty-eight states; births are reported early enough to be of assistance in preventing blindness in seventeen states; the question as to whether or not measures were taken to prevent blindness is included in the birth certificate in nineteen states; free prophylactic outfits are distributed in twenty-two states; use of prophylactic is compulsory in nineteen states, and strongly recommended in an additional four states; popular educational leaflets relating to preventable blindness are distributed by state health departments in 29 states. The National Committee for the Prevention of Blindness in its *News Letter*, December, 1918, prints a tabulated summary of state laws and rulings relating to the prevention of blindness from babies' sore eyes.

INFLUENZA EPIDEMIC AT THE CHICAGO STATE HOSPITAL

EDWARD A. FOLEY, M.D.
CHICAGO

Fifteen days following the outbreak of influenza at the Great Lakes Station, the disease made its appearance at the Chicago State Hospital. The first patient was a voluntary worker in the occupational therapy department. So far as can be learned, this young woman had not come in contact with an active case of influenza. However, she had been to Chicago. Following this case, both patients and employees rapidly began to show infection. The total number treated during the next six weeks was 507 inmates and fifty-two employees. Of the 507 patients ill with the disease, 349 were males and 158 females. The total number of deaths among the inmates was eighty-one or 16.2 per cent. The incidence of death according to sex was: males, forty-eight, or 13.7 per cent., and females, thirty-three, or 20.8 per cent.

DISTRIBUTION OF THE DISEASE

The colored population of the institution is made up of 139 people, seventy-three of the 139 being males and sixty-six females. The number of colored patients showing symptoms of influenza was not very large. Six men and seven women were admitted to the isolation wards. All the men recovered. One woman died; one developed pulmonary tuberculosis; five recovered.

The praecox group constitutes by far the majority of our population; consequently one would look for a larger number of this type involved than any other. Table 1 shows the incidence of the disease among the various psychoses:

TABLE 1.—INCIDENCE OF INFLUENZA ACCORDING TO PSYCHOSES

Psychoses	Number
Dementia praecox group	193
Epileptic	55
Alcoholic (all types)	53
Mental defective (all types)	49
Organic brain disease (including paresis)	45
Senile dementia	35
Undiagnosed psychoses	43
Manic-depressive group	34

Next to the praecox group, the epileptics were most severely affected. The males of this class more easily become victims than the females. Within the first week of the onset of the disease, the greater part of the male epileptics were confined to bed. The mortality among this type was very small.

The ages of those ill are given in Table 2; the number of days ill in the isolation ward, in Table 3.

Among the fifty-two employees who became ill, the mortality was only 3.8 per cent.

INFLUENCE OF ISOLATION

The farm ward, located some distance from the cottages and the main building, houses seventy men. These men rarely come in contact with other patients, and are outdoors most of the time. Influenza failed to claim any of this colony. Other wards in the hospital group failing to show infection were wards wherein female patients are confined. In one of these units are housed our laundry workers. The women go back and forth to the laundry four times daily. They rarely come in contact with other inmates, and only with those employees with whom they work.

The second female unit not showing infection (C W 12) constituted a group that worked in the hospital building and sleep in C W 12 at night. One of this group became infected in the following manner: One of her friends was admitted to the isolation ward with a frank case of influenza. Through a mistake the patient gained admission to the ward to visit her friend. She was discovered at the bedside without having provided herself with a mask. That night she did not return to Ward C W 12, but slept on the lower floor of the hospital building. Two evenings following her visit, she was reported to have an elevation of temperature. She was immediately removed to the isolation ward for observation. In three days she began to show signs of pulmonary involvement, and five days later she died from a bronchopneumonia. This case cannot therefore be charged to Ward C W 12.

TABLE 2.—AGE INCIDENCE

Age	Number
Under 20	20
From 20 to 30	172
From 30 to 40	118
From 40 to 50	84
From 50 to 60	64
From 60 to 70	41
From 70 to 80	5
Over 80	5

The third unit that escaped infection was Ward A 1, more or less isolated from the other wards of the main building.

USE OF THE FACE MASK

All employees, helpers, nurses and physicians in attendance on influenza patients always wore the face mask. Only three nurses became infected with influenza while on duty in the isolation ward. The attacks were mild in nature. I believe that these nurses became infected by being careless regarding the masks.

PROGNOSIS

From our observation of the cases under treatment we could not judge the patient's condition by the temperature. Some patients appeared to be comfortable with a high temperature, while others whose temperature had been normal or near normal for several days died. The pulse and respiration, like the temperature, were often misleading. Each patient had to receive as much individual attention as could be given. Epistaxis was noted in about 20 per cent. of the cases. Contrary to a statement that those cases in which nosebleed occurred had a favorable prognosis, our observation was that this condition is not a criterion on which to judge the outcome of a case. Some of the patients showing this sign died, while others recovered. It was noticed that epistaxis occurred when the temperature was high—from 104 to 105 F. In the women patients early menstruation was a feature; this was noted especially among women employees. Several of the employees describe delusional experiences while ill. During convalescence, otitis media developed in several of the inmates and employees.

TABLE 3.—DURATION OF ILLNESS*

Duration	Number
From 1 to 5 days	139
From 5 to 10 days	127
From 10 to 15 days	84
From 20 to 25 days	44
From 25 to 30 days	10

* Forty-eight patients were still in the isolation ward at the time of the compilation of this report.

EQUALITY OF DISTRIBUTION

The wards housing the more deteriorated type of cases did not show any more infections than those in which the more robust inmates reside. In a ward known as D W 3, there are housed seventy-four male patients of various types, showing deterioration. From their lowered mentality and physical status, one would naturally expect that among this type of individuals infection would find many victims. During the epidemic this ward was watched with a great deal of anxiety. When the wave of the epidemic had passed, we were pleased to note that out of the seventy-four inmates of this ward, only eleven were sent to the isolation wards suffering from influenza.

How to explain why we did not have more cases of illness among those of lowered mental status, which consequently lessens resistance, still remains one of the mysteries of the epidemic. In Wards C W 13, 14 and 15, known as the "industrial wards," housing male patients who are outdoors a great deal, the number of cases of infection was small. The ward showing the most cases was Ward D W 4, housing the epileptics.

The infection was, however, distributed throughout the institution. It is difficult to understand why we did not have more cases. Perhaps this was due to the fact that persons showing signs of illness were immediately transferred to isolation wards, and all precautions were taken to prevent further transmission of infection.

RECURRENCES

Two persons who had had influenza in the first epidemic were readmitted to the isolation wards: In the first patient, admitted for the first time, October 9, the disease ran a typical course, and the patient was discharged, October 18. The patient was readmitted, December 5, with frank influenza, and the temperature ran an irregular course until December 15, since which time it has been normal. The second patient, first admitted to the isolation wards, October 17, and discharged, November 8, was readmitted, December 15, and died, December 23, of bronchopneumonia.

CONTRIBUTION TO THE ETIOLOGY OF YELLOW FEVER *

HIDEYO NOGUCHI, M.D.
NEW YORK

During the past four months (from July to November, 1918), I have been engaged at Guayaquil, Ecuador, under the auspices of the International Health Board of the Rockefeller Foundation, in the study of the etiology of the yellow fever prevalent there. I wish at this time to record briefly some of the more significant results of this study, pending the fuller publication of the details which will follow.

In the later paper acknowledgment will be made of the cordial and indispensable official and professional cooperation of the National and Municipal Health authorities in Guayaquil, especially that of Dr. W. Pareja, the director of the Yellow Fever Hospital, and Dr. León Becerra, director-general of the health department of Ecuador.

In six out of twenty-seven cases studied, the injection into guinea-pigs of the blood of yellow fever patients, after a period of incubation, induced in these animals first a rise of temperature with the appearance of rapidly increasing albumin and casts in the urine. Simultaneously the conjunctivae, ears and soles became highly hyperemic, and leukopenia set in. A fall of temperature by lysis soon occurred, with the development of distinct and gradually deepening yellow pigmentation of the sclerae, skin and viscera. During this period hemorrhages from the mucous membranes of the nose, mouth and gums occasionally took place, and petechial hemorrhages of the skin, muscles, heart and kidney were often observed. Congestion and hemorrhages were almost always present in the mucous membranes of the gastro-intestinal tract, giving the contents the dark, tarlike appearance of so-called black vomit, and the lungs showed large and small hemorrhages. The liver and kidneys showed petechial hemorrhages and evidences of degeneration. Intense general jaundice, cholemia, oliguria with abundant albumin, casts and bile pigment, and sometimes anuria, marked the later stage of the infection. With the development of these manifestations, the animals usually died in coma or convulsions.

Dark field examination of the blood, liver and kidneys of these inoculated animals revealed the presence of an organism whose morphologic characters closely resembled those of the organism (*Leptospira*) previously described in cases of infectious jaundice.[1]

By the use of special methods the organism found in the blood, liver and kidneys of animals inoculated with the blood of yellow fever patients has been obtained in pure culture.

In some instances the direct dark field examination of the blood and liver of yellow fever patients in Guayaquil showed the presence of a leptospira indistinguishable from that described as occurring in the blood and viscera of the experimentally infected guinea-pigs. By special methods, pure cultures of this organism were obtained directly from the blood of yellow fever patients in a limited number of cases.

This organism does not grow on ordinary bacterial culture mediums, and when grown on the special mediums it induces no macroscopic changes of the latter and hence may be easily overlooked. Only by a very thorough dark field examination of such cultures can the occurrence of growth be ascertained.

By the inoculation of the blood and emulsions of the liver and kidneys of infected guinea-pigs, the infective agent has been conveyed from animal to animal without loss of virulence through successive series (now numbering eighteen); and pure cultures of the organism are obtainable during the course of the infection from any animal of these series.

When cultures of the organism, derived either from the inoculated animals or directly from the blood of a yellow fever patient, were inoculated into guinea-pigs, monkeys (marmosets) and puppies, symptoms and lesions were induced which were similar to those outlined as occurring from a successful inoculation of guinea-pigs directly with blood from yellow fever patients. The organism recovered in pure culture from these inoculated animals has retained its original characteristics.

Many of the guinea-pigs that did not succumb to the inoculation with the blood from yellow fever patients showed definite febrile reaction, some with a trace of jaundice, for several days, but soon returned to normal. Most of these guinea-pigs later proved resistant to infection with virulent organ emulsions or with cultures of the organism; while control animals (normal guinea-pigs or those inoculated previously with blood of patients suffering from other diseases than yellow fever) died, with characteristic symptoms and lesions.

[1] Inada, Ido, Hoki, Kaneko and Ito: J. Exper. Med. **23**: 377, 1916. Noguchi: Ibid. **27**: 575, 1918.

A positive Pfeiffer phenomenon was obtained in the majority of instances with serum derived from convalescents from yellow fever in Guayaquil when tested with the organism (*Leptospira*) isolated from the yellow fever cases or from infected animals. This was also true of the serum of animals that survived experimental infection.

Characteristic symptoms and lesions were induced in susceptible animals by inoculation with the filtrates obtained by passage through Berkefeld filters V and N of the blood of experimentally infected animals, and the emulsions of the liver and kidney of these animals and of the cultures of the organism. *Leptospira* was demonstrated in the blood or visceral organs of the animals thus inoculated.

The filtrability of the infective agent of yellow fever has been observed by earlier investigators.[2]

RELATION OF INFLUENZA BACILLUS TO THE RECENT EPIDEMIC OF INFLUENZA *

FREDERICK T. LORD, M.D.
ARTHUR C. SCOTT, Jr., M.D.
AND
ROBERT N. NYE, M.D.
BOSTON

Pfeiffer[1] found influenza bacilli in all fresh uncomplicated cases of influenza in almost pure culture. His investigation was carried out for the most part on persons seeking hospital care for the more severe attacks of bronchitis and bronchopneumonia. Influenza bacilli were found only in influenza patients with and convalescent from influenza, a fact of great importance in Pfeiffer's opinion in establishing the specific nature of the organism. In three cases of bronchopneumonia complicating diphtheria, organisms closely resembling influenza bacilli were found but somewhat larger and with an outspoken tendency to the formation of longer thread forms. Such organisms he called pseudo-influenza bacilli.

Subsequent workers have failed to confirm the presence of a group of pseudo-influenza bacilli. Such differences as Pfeiffer described are to be regarded as variations in morphology in different generations and on different culture mediums.

In the period immediately following the great pandemic of 1889-1890, and subsequent to Pfeiffer's work, influenza bacilli were found by different workers in a considerable proportion of cases in local outbreaks of influenza, but only rarely in such constancy as he had described. In the widespread epidemic in the United States in 1907-1908, Lord[2] found influenza bacilli in practically pure culture in only three of twenty cases. Among twenty-three cases, Davis,[3] from Chicago, found the organism in only four.

Between August, 1902, and January, 1904, Lord[4] investigated 186 sputums from patients with acute and chronic infection of the respiratory tract, exclusive of tuberculosis. As shown in Table 1, organisms having the morphology and staining reaction of influenza bacilli, mixed with other bacteria, were found in smears in 110 (59 per cent.). In fifty-six cases (30 per cent.) the organisms were shown by culture to conform in all respects to Pfeiffer's bacillus. In forty-seven cases (25 per cent.) they were in overwhelming numbers. The cases were quite evenly distributed over the eighteen months during which the investigation was conducted, and no epidemic of acute respiratory infection prevailed during this period. Patients with chronic respiratory infection were found to harbor the influenza bacillus for years in the sputum. Many such cases seemed to have begun insidiously without an acute attack at the onset. The acute cases in which influenza bacilli existed as a practically pure infection in the interepidemic period presented no clinical or pathologic difference from those with other organisms and in which no influenza bacilli could be found. The symptoms of onset, the course and termination were practically the same in those with and those without influenza bacilli.

TABLE 1.—INCIDENCE OF INFLUENZA BACILLI IN RESPIRATORY INFECTIONS DURING INTEREPIDEMIC PERIOD, 1902-1904

		Influenza bacilli

Normal individuals are known to harbor influenza bacilli. Rosenthal[5] found them in the larynx and trachea in about one of six normal persons or those with nonrespiratory disease. Davis[3] found them in small numbers in swabs from the throat in two (10 per cent.) of twenty normal persons. Holt[6] reports the presence of influenza bacilli in 49 (19 per cent.) of 254 persons with nonrespiratory disturbance.

TABLE 2.—INCIDENCE OF INFLUENZA BACILLI IN NORMAL PERSONS DURING EPIDEMIC PERIOD

pharyngeal wall of thirty-four young men, members of the Harvard Students' Army Training Corps at Cambridge, none of whom gave a history of any illness during the preceding three months. In this training corps the incidence of influenza was 9.3 per cent., as shown by Minot and Loeb.[7] This proportion was very low compared to that in other groups in this community. As shown in Table 2, organisms resembling influenza bacilli in morphology and staining reaction were demonstrated in fourteen (41 per cent.) of the thirty-four cases. Influenza bacilli were found in culture in twenty-six (76 per cent.). They were in overwhelming numbers in ten cases (29 per cent.).

Through the kindness of Dr. J. H. Wright, complement fixation tests were made on the blood in twenty-seven of the Students' Army Training Corps cases, both with a monovalent and with a polyvalent influenza bacillus antigen obtained from influenza cases during the epidemic. No difference was noted in the result with the monovalent and the polyvalent antigen. In seventeen cases, there was a correspondence in the positive swab and the positive complement fixation test. In four cases, both were negative. In four cases, the throat swab was positive and the complement fixation test negative. In two cases, the complement fixation was positive and the throat swab negative. Though no definite conclusions can be drawn, the findings are suggestive of a response in the blood to the presence of influenza bacilli in the throat as shown by the complement fixation test.

It has been shown that influenza bacilli are frequently present in the material from the respiratory tract of patients with tuberculosis, measles, scarlet fever, diphtheria and varicella, as shown in Table 3.

These organisms may be present in from 19 to 100 per cent. of cases. In the study of postmeasles bronchopneumonia due to *Streptococcus hemolyticus,* Cole and MacCallum[8] found influenza bacilli in thirteen (76 per cent.) of seventeen cases.

Investigation of the recent epidemic was begun at the height of the outbreak and lasted from September 28 to October 24. Only patients in hospital with the more severe types of infection were studied. It was difficult to distinguish between bronchitis and bronchopneumonia in certain cases. Of thirty-eight cases, eight were classed as influenzal bronchitis or questionable bronchopneumonia and thirty as influenzal bronchopneumonia, thus duplicating the character of the material on which Pfeiffer made his investigation.

A typical sample of mucopurulent or mucopurulent and bloody expectoration was obtained from each case. Carefully selected particles of this fresh material were smeared, stained and examined. Organisms resembling influenza bacilli in morphology and staining reaction were thus found mixed with other bacteria in thirty-two (84 per cent.) of thirty-eight cases, as shown in Table 4.

TABLE 4.—INCIDENCE OF INFLUENZA BACILLI IN HOSPITAL PATIENTS DURING 1918 EPIDEMIC

		Influenza bacilli					
		Mixed with Other Organisms in Smears		In Cultures*		In Overwhelming Numbers in Culture	
No. of Cases	Source of Material	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
38	Sputum	32	84	30	78	14	36
15	Lung tap, postmortem, 9 cases	..	..	6	66	1	11
	Chest tap, antemortem, 6 cases	..	..	4	66	2	33
4	Lung scraping, postmortem	..	..	1	25		

* The colonies of influenza bacilli were tested for growth on plain agar in twenty-seven cases. No growth was obtained.

Cultures on blood agar were made of washed particles of sputum, and the prevalence of influenza bacilli was noted in thirty-eight cases. Colonies of influenza bacilli with those of other bacteria were found in thirty (78 per cent.) of the cultures. In fourteen cases (36 per cent.), influenza bacilli were present in overwhelming numbers on comparison with other organisms. Varying numbers of organisms resembling *Micrococcus catarrhalis,* the pneumococci, pyogenic cocci, hemolyzing and nonhemolyzing streptococci, etc., were found mixed with the colonies of influenza bacilli.

Lung tap in the involved region immediately after death was made in nine cases. Influenza bacilli were found in culture from this material in six (66 per cent). They were present in overwhelming numbers in one (11 per cent.). In this case they were in pure culture. In all the other cases they were mixed with other organisms. Serofibrinous or purulent fluid obtained from the chest of patients with influenzal bronchopneumonia was examined in six cases. Influenza bacilli with other organisms were found in culture in four (66 per cent.), and in overwhelming numbers in two (33 per cent.). *Postmortem* scrapings from the involved part of the lung showed influenza bacilli with other organisms in one (25 per cent.) of four cases.

The finding of influenza bacilli in the wards cannot be ascribed to cross infection, as influenza bacilli were present in the sputum of eight (88 per cent.) of nine cases examined within twenty-four hours of entrance, a proportion higher than the general incidence (78 per cent.) of influenza bacilli in the series of cases in which sputum examinations were made.

Concerning the pathogenic power of influenza bacilli, the evidence is insufficient to reach a conclusion; but, in spite of negative animal experiments, their presence in enormous numbers to the practical exclusion of other organisms in certain cases in the sputum during life [illegible] the lung tissue after death suggests that they are important contributory or principal factors in causing pathologic changes in man. Their occasional presence as the sole apparent cause of meningitis and suppurative lesions in various parts of the body is still further suggestive of their pathogenic power.

[7] Minot, G. R., and Loeb, R. F.: Boston M. & S. J. **179**:665, 1918.

[8] Cole, R., and MacCallum, W. G.: Pneumonia at a Base Hospital, J. A. M. A. **70**:1146 (April 20) 1918.

The most interesting question concerns the specificity of influenza bacilli in relation to *influenza.* Pfeiffer's most convincing argument, in the absence of positive animal experiments, was their presence only in patients with and convalescent from influenza. If the organism were the cause of epidemic and pandemic influenza, it must, however, contrary to Pfeiffer's contention, prevail during interepidemic periods. Its biologic peculiarities suggest that it cannot exist for long under any ordinary conditions apart from the human host and that it must be maintained in chronic carriers or by repeated transfer from person to person. An occurrence in 59 per cent. by microscopic examination, 30 per cent. by culture, and 25 per cent. in overwhelming numbers, in acute and chronic nontuberculous respiratory infections during interepidemic periods would serve to bridge the gap between and keep the organism alive for recurring outbreaks. During the interepidemic period, however, those cases which show influenza bacilli as a practically pure infection present no clinical or pathologic difference from respiratory infection in which other organisms predominate and in which influenza bacilli cannot be found.

The influenza bacillus is part of the flora of the normal respiratory tract, investigations previous to the recent epidemic having shown it to be present in from 10 to 19 per cent. In our series of thirty-four normal individuals, examined during the epidemic period, influenza bacilli were found in 76 per cent. by culture and in 29 per cent. in overwhelming numbers. Means of identifying influenza bacilli are limited to the morphology, staining reaction and cultural peculiarities of the organism, and it cannot be stated whether or not the bacilli harbored by normal persons are of the same type as those found in the presence of a respiratory disturbance; but when judged by these criteria they appear to be the same. The frequency with which they are present in normal individuals may be regarded as determining their incidence in diseased conditions.

The influenza bacillus is a frequent finding in the secretions from the respiratory tract under such a variety of conditions as pulmonary tuberculosis (33 per cent.), measles (from 19 to 78 per cent.), scarlet fever (39 per cent.), diphtheria (60 per cent.) and varicella (100 per cent.). The organism certainly cannot be regarded as of etiologic importance in these diseases, but may be of significance as a secondary invader.

The character and distribution of the recent epidemic of influenza indicate that it is to be regarded as the same disease that has prevailed in epidemic form at intervals during the past four centuries and last occurred as a great pandemic in 1889-1890. While much doubt has been expressed concerning the relation of Pfeiffer's bacillus to epidemic influenza, no definite conclusion could be reached until an outbreak like that through which we have just passed afforded the necessary opportunity for investigation. Our material, like Pfeiffer's, comprised the more severe cases of bronchitis and bronchopneumonia in hospital. We have been unable to confirm his constant finding of the organism in almost pure culture. It has been demonstrated in our epidemic series in 84 per cent. by microscopic examination, in 78 per cent. by culture, and in 36 per cent. in overwhelming numbers.

Comparison with the findings by similar methods in an interepidemic period of 59 per cent. by microscopic examination, 30 per cent. by culture and 25 per cent. in overwhelming numbers, indicates that there is no considerable rise at least in the most important group, namely, that in which the organisms were present in overwhelming numbers. It is a common invader of the normal respiratory tract and may be found in a considerable proportion of cases with pulmonary tuberculosis and the contagious diseases of childhood. There seems to be no justification for the belief that the epidemic was due to the influenza bacillus, which is probably a secondary invader and bears about the same relation to the influenza cases as to respiratory infections of a different sort.

THE PRODUCTION OF MENINGITIS BY RELEASE OF CEREBROSPINAL FLUID

DURING AN EXPERIMENTAL SEPTICEMIA: PRELIMINARY NOTE *

LEWIS H. WEED, M.D.
PAUL WEGEFORTH, M.D. (San Diego, Calif.)
JAMES B. AYER, M.D. (Boston)
Captains, M. C., U. S. Army
and
LLOYD D. FELTON, M.D.
Contract Surgeon, U. S. Army
BALTIMORE

In the course of the experimental study of meningitis, it was found that a certain strain of *B. mucosus-capsulatus* possessed particular virulence within the meninges of laboratory animals. A typical acute and fatal leptomeningitis was produced by the direct subarachnoid injection of very small numbers of these organisms; the affected animals showed characteristic signs of meningeal infection, dying in from eight hours to five days. The number of these bacilli necessary for the production of such an infection was far smaller than with any other strain or class of organisms tested. The particular strain of *B. mucosus-capsulatus* used in these observations is, according to the classification of Perkins, *B. lactis-aerogenes,* being differentiated from others of the group by the sugar reactions. It is an encapsulated, nonspore-forming, gram-negative, nonmotile bacillus, with a tendency to occur in varying lengths of chains. This organism was isolated from the lungs and blood of a patient dying of bronchopneumonia.

Later experiments leading to another end were undertaken: These concerned the intravenous injection of this organism in doses of from 0.5 to 1 c.c. of a twenty-four hour broth culture. None of these cats developed meningitis, but remained normal throughout the period of observation. In one case, shortly after such experimental injection into the blood stream, cerebrospinal fluid was removed by puncture. The next day the animal showed signs of meningeal irritation, and a second puncture with withdrawal of cerebrospinal fluid was done. The fluid was definitely turbid, contained 5,800 white blood cells, and yielded a positive culture of *B. mucosus-capsulatus*. In the smear from this fluid many bacilli were present. The animal died in twenty-eight hours, and at necropsy a typical exudative leptomeningitis was found.

---

* From the Army Neurosurgical Laboratory, Johns Hopkins Medical School.

MENINGITIS BY B. MUCOSUS-CAPSULATUS INTRAVENOUSLY AND WITHDRAWAL OF SPINAL FLUID

Observations on cats were immediately devised to test out the possible relationship of this withdrawal of cerebrospinal fluid during an artificial septicemia to the later production of a meningitis. The series were so arranged that the control animals were given double the intravenous dose of *B. mucosus-capsulatus* (usually 0.5 c.c. of a twenty-four hour meat infusion broth culture). These control cats remained normal and showed no signs of meningeal infection, and were usually killed at the end of a month for histologic control. The other cats in this series were given the unit dose of organisms intravenously (usually 0.25 c.c. of the same culture), and two minutes afterward, cerebrospinal fluid was withdrawn. In the routine experiment, from 1 to 2 c.c. of fluid was permitted to escape, and the animal then allowed to recover from the anesthetic. As contrasted the next day with the control cat, which, though receiving double the intravenous dose, was normal and active, the punctured cat would exhibit signs of meningeal infection. Customarily within twenty-four hours, the typical signs of such meningeal involvement would be present; the animal would be somewhat hypersensitive, ill and cautious, and would move only on urgent necessity. On retraction of the head, a more or less profound extensor spasm with all four legs outstretched in marked rigidity would be caused. The tendency toward convulsions would become more outspoken as time elapsed, and spontaneous seizures would be noted. During such a spasm death might occur, or the animal might finally go into a coma and die without further signs of meningeal irritation. Pathologically, an acute exudative leptomeningitis would be found.

Subsequently, the procedure outlined above has been repeated in scores of experiments; the production of meningitis by intravenous inoculation followed by release of cerebrospinal fluid has been so certain and so regular that it has become our chief method for the experimental production of the infection. The work has been controlled in many ways, in addition to the routine method of giving one animal in the series an intravenous injection of double amount but without puncture; in a more complete report of this work the cultural controls will be included.

The release of cerebrospinal fluid may be brought about by either lumbar or occipito-atlantoid puncture. The end-result is identical, and approximately the same amount of fluid may be withdrawn by either method. No appreciable difference in the production of meningitis by intravenous inoculation, followed by lumbar puncture, and that by occipito-atlantoid puncture has been noted. Release of fluid by both procedures, with proper dosage of the organism within the blood stream, results invariably in the infection of the meninges. Puncture through the occipito-atlantoid ligament, as practiced by Dixon and Halliburton, is an ideal method for the removal of cerebrospinal fluid in the laboratory mammals.

That this phenomenon of an acute meningitis following intravenous inoculation with release of cerebrospinal fluid was not peculiar to cats was demonstrated by a series of experiments on rabbits, guinea-pigs, white rats and monkeys. In each of these species, the control was given the same or double the intravenous dose as the animal from which the cerebrospinal fluid was removed at the height of the artificial septicemia. In every case the control remained well and normal until killed, while the animals from which spinal fluid was removed promptly developed a typical meningitis with death in ninety-six hours or less. In the two monkeys at our disposal, the same procedure was carried out: the control (receiving only the intravenous injection) remained normal for seven months, dying finally of pulmonary tuberculosis, while the monkey receiving the intravenous injection followed by the withdrawal of cerebrospinal fluid died in fifty-four hours with typical signs of meningitis. The two monkeys were punctured forty-eight hours after the initial injection; in the control, the cerebrospinal fluid contained no white cells, and the culture was negative, while the other had 14,000 white blood cells and yielded a positive culture.

The time relations between the withdrawal of cerebrospinal fluid and the intravenous injection of organisms are of importance. In no case has a meningitis developed when the cerebrospinal fluid was released thirty or more minutes before the intravenous inoculations. If the puncture is done, however, only a few minutes before the inoculation into the blood stream, infection of the meninges occurs as in the other observations in which routine withdrawal of fluid is accomplished at the height of the artificial septicemia. Somewhat analogous are the findings in the time relationship between initial introduction of organisms intravenously and the subsequent withdrawal of fluid.

During the height of a suitable artificial septicemia, the release of fluid invariably causes a meningitis. In one series of experiments, the punctures were delayed for varying periods after the intravenous injection. Animals from which cerebrospinal fluid was withdrawn at least three hours after the intravenous injection developed meningitis. But also animals receiving somewhat larger intravenous doses could not be punctured five hours afterward without developing infection of the meninges. Hence a striking time relation between the degree of the artificial septicemia and the withdrawal of cerebrospinal fluid seems established. It must be assumed that following the intravenous injections of *B. mucosus-capsulatus* the number of bacteria in the circulating blood is constantly diminishing so that in practically all cases of simple intravenous injection the blood is sterile in twenty-four hours. Consequently, delay in removal of cerebrospinal fluid is comparable to administration of a smaller intravenous dose of organisms. Apparently the number of organisms circulating within the blood stream at the time of puncture is one of the crucial factors in determining the infection of the meninges.

Other observations were made to determine how soon this infection of the meninges occurs after the release of cerebrospinal fluid during the height of the septicemia with *B. mucosus-capsulatus*. In these typical experiments the animals were killed one hour, two hours, four hours and six hours after the experimental injection and puncture. The membranes of the central nervous system were then examined in fresh by means of smears taken from the subarachnoid space, and the findings later controlled by histologic sections. In the one hour case after repeated search one or two large bacilli, morphologically identical with *B. mucosus-capsulatus*, were found in the cerebral leptomeninges but not elsewhere within the meninges. The two hour specimen yielded bacteria only in the cranial portion of the pia-arachnoid, but in considerable numbers. Practically no cellular exudation was present.

Many polymorphonuclears and mononuclears were present in the four and six hour animals; the infection at first was largely within the cerebral meninges, but apparently to a lesser degree the spinal portion of the subarachnoid space was involved. These findings indicate that the infection of the meninges must occur almost immediately after the release of cerebrospinal fluid during such an artificial septicemia.

Pathologically, the meningitis produced by this means is comparable to infection of the leptomeninges in man. In these acute experimental infections there occurs a more or less widespread distribution of purulent matter throughout the subarachnoid space, obliterating all characteristic markings and obscuring contours. With the discoloration due to pus and hemorrhage, there is associated a fairly constant swelling of the nervous system itself, rendering tense the dura of both brain and spinal cord. In a great majority of cases (particularly those under forty-eight hours' duration) the gross distribution of the exudate is almost entirely cerebral; but in a small percentage of the early cases, the exudate may be wholly confined to the spinal meninges. In the more prolonged infections, the involvement of the subarachnoid space is customarily universal. Microscopically, the exudate consists of polymorphonuclear leukocytes, large mononuclear cells, a few phagocytes, and the infecting organisms. The perivascular spaces of the cerebral cortex are early infected; the exudate here is of the same character as in the subarachnoid space. In the very virulent infections, the substance of the brain and cord may be involved as in similar processes in man.

It is of importance to determine whether the meningitis produced by intravenous inoculation and release of cerebrospinal fluid is the result of infection due to a possible leakage of blood along the track of the needle into the subarachnoid space. The evidence at the present time indicates most strongly that the determining factor in the infection is probably the pressure of the spinal fluid with associated vascular alterations. This conclusion is based in part on observations such as these:

(*a*) In the majority of cases, the exudate is largely cerebral and does not represent the characteristic distribution of a spread from a local point of infection.

(*b*) Cultures of the cerebrospinal fluid removed during the artificial septicemia and when free from blood contamination have proved negative.

(*c*) The withdrawal and replacement of the fluid, just before intravenous inoculation, have not resulted in the production of a meningitis though it is impossible to prevent leakage of the fluid outward along the path of the needle.

(*d*) Similar withdrawal of fluid during the septicemia, but replacement after two minutes, has not prevented the development of a meningitis.

In addition, other factors, to be reported later, argue strongly for the view that the infection of the meninges under such circumstances is the result of pressure alterations within the central nervous system.

PRODUCTION OF MENINGITIS SIMILARLY WITH OTHER ORGANISMS

With such results following the intravenous injection of *B. mucosus-capsulatus* with release of cerebrospinal fluid, experiments were undertaken to ascertain if the same procedure, but with other organisms, would produce meningitis. The difficulty has been that with the ordinary cultures in a laboratory, the intravenous toxicity is high compared to the intraspinal. However, it has been possible to repeat these experiments and confirm the finding on the cat with two other organisms—*B. pyocyaneus* and *B. paratyphosus* B. On rabbits a similar result has been obtained with a strain of streptococci procured from an army camp. Three control rabbits in one of these series were given intravenous doses of this organism, 1 c.c. each of a twenty-four hour broth culture, diluted 1 : 1,000, 1 : 2,000 and 1 : 5,000, respectively. Similar doses were given to three other rabbits of the same size and weight, but these were in addition each subjected to the release of about 1 c.c. of clear cerebrospinal fluid by occipito-atlantoid punctures. Two of the latter animals were dead on the next morning; at necropsy an acute meningitis was found. The third animal showed within twenty-four hours a more chronic form of meningitis, dying on the seventeenth day; typical infection of that duration was found postmortem. The three control animals remained normal until killed on the twenty-fifth day; the central nervous systems of these animals showed no abnormalities.

VIRULENCE AND NUMBER OF ORGANISMS

The biologic significance of the release of cerebrospinal fluid during an artificial septicemia seems established by the production, in this laboratory, of a typical meningitis with four different organisms. The conditions for the successful production of such an experimental meningitis concern two factors, both apparently of determining importance. In the first place, it seems established that the organism used must possess relatively great virulence within the meninges and be capable of multiplication there even when in small numbers. The strain of *B. mucosus-capsulatus* has best fulfilled this requirement when introduced into the subarachnoid space of the common laboratory mammals; its virulence in these animals is probably comparable to that of organisms causing meningitis in man. The other important condition deals with the number of organisms circulating in the blood stream at the time of the release of the spinal fluid; if this is not great enough, no infection will take place.

It must not be assumed from the statements made that a meningitis may not be produced by *B. mucosus-capsulatus* after simple intravenous injection. Such a meningitis has been caused by the introduction within the blood stream of massive doses of the organism. The amount necessary to produce such a meningitis is at least four to six times the customary intravenous injection; such animals are killed usually by the septicemia and not by the meningitis. Many of these animals died from the overwhelming intravenous injection without development, as shown by later necropsy, of any meningeal infection at all. With massive doses, however, all parts of the body may be infected: the meningitis is merely a part of the general infection. This bears only slight relation to the phenomenon of the localization of an intravenous infection within the meninges by release of cerebrospinal fluid.

CONCLUSION

It seems established, then, that the intravenous injection of a sufficient number of organisms, virulent within the meninges, will produce a typical leptomeningitis, if the cerebrospinal fluid is withdrawn during the artificial septicemia. The clinical significance of this finding seems great, and it becomes necessary to ascertain if the same relation between the withdrawal of cerebrospinal fluid during a septicemia and the subsequent development of a meningitis will hold in man. Data relating to this point are being assembled.

A STAIN FOR INFLUENZA BACILLI IN TISSUES

A COMBINATION OF GOODPASTURE'S AND WEIGERT'S STAINS *

W. G. MacCALLUM, M.D.
BALTIMORE

Since the bacillus of Pfeiffer commonly occurs in association with other organisms in the lungs and other tissues, it is difficult to make the organisms appear distinctly in stained sections. There are many methods by which they or any other gram-negative organisms can be stained in the tissues (Nicolle, Giemsa, etc.), but these require very careful differentiation and then leave all bacteria, whether gram-negative or gram-positive, stained alike. One may, of course, stain all bacteria in one section and only the gram-positive organisms in another, and subtract the result in one from that in the other, so as to gain an idea of the number and distribution of gram-negative organisms; but it is very desirable to be able to bring out in the same section the gram-negative bacteria in one color and the gram-positive in another.

The stain devised by Dr. Goodpasture furnishes the requisite red stain for all bacteria. This used alone gives results comparable with those of Giemsa's or Nicolle's method but is suitable for combination with Weigert's stain because of its contrasting color.

Dr. Goodpasture's paper giving his method will not be published until April, but he most kindly allows me to use his formula in describing the combination which includes his stain, "in view" (as he writes) "of the present need of such a method."

PROCEDURE

Fixation should be in Zenker formaldehyd solution, and very thin paraffin sections should be used.

1. Stain for from ten minutes to one-half hour or more in Goodpasture's stain, which is:

	Gm. or C.c.
30 per cent. alcohol	100
Basic fuchsin	0.59
Anilin	1.0
Phenol crystals	1.0

2. Wash in water.
3. Differentiate in 40 per cent. formaldehyd solution. This requires only a few seconds. The bright red color washes away and gives place to a clear rose.
4. Wash.
5. Counterstain in saturated aqueous picric acid. The section remains until it assumes a *purplish yellow*, about three to five minutes or less.
6. Wash in water.
7. Differentiate in 95 per cent. alcohol. The red reappears and some of it is washed out. Some of the yellow of the picric acid is also washed out.
8. Wash in water.
9. Stain in Stirling's gentian violet five minutes or more.
10. Wash in water.
11. Gram's iodin solution.
12. Blot dry without washing.
13. Anilin and xylene (equal parts) until no more color comes away.
14. Two changes of xylene.
15. Balsam.

Gram-negative organisms stain red, gram-positive blue. The tissues stain brilliantly in shades of red and purple. Fibrin is, of course, sharply stained, and the granules of mast cells are prominent as red or purplish coccus-like bodies.

The method should be useful in the study of infections of exposed surfaces, such as the intestinal mucosa and the urinary bladder, with gram-negative organisms. The lesions of dysentery, typhoid fever and many other similar conditions might be studied with advantage by this method.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

CHLORINATED EUCALYPTOL-SQUIBB.—Eucalyptol, chlorinated at ordinary (room) temperature.

Actions and Uses.—Chlorinated eucalyptol-Squibb is used as a solvent for dichloramine-T.

Dosage.—Solution of dichloramine-T in chlorinated eucalyptol-Squibb should preferably be made as required and without the use of heat. If kept in the dark, stock solutions may be used for thirty days.

Prepared by E. R. Squibb & Sons, New York. No. U. S. patent or trademark.

Eucalyptol is treated with potassium chlorate and strong hydrochloric acid. After standing twelve hours at room temperature, the chlorinated eucalyptol is washed, first with water and then with sodium carbonate solution. Dry sodium carbonate is then added to the chlorinated eucalyptol and this allowed to stand for twenty-four hours. The chlorinated eucalyptol is filtered and dried by addition of calcium chloride (Jour. A. M. A., July 7, 1917).

Chlorinated eucalyptol has the color and odor of eucalyptol.

ARSPHENAMINE (See New and Nonofficial Remedies, 1918, p. 44).

Arsaminol.—A brand of arsphenamine.

Manufactured by the Takamine Laboratory Inc., New York, under U. S. patent Nos. 986,148 (*March 7, 1911*; expires 1928), 1,081,897 (Dec. 16, 1913; expires 1930), 1,081,592 (Dec. 16, 1913; expires 1930), and 1,116,398 (Nov. 10, 1914; expires 1931) by license of the U. S. Federal Trade Commission.

Arsaminol 0.1 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.1 Gm.

Arsaminol 0.2 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.2 Gm.

Arsaminol 0.3 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.3 Gm.

Arsaminol 0.4 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.4 Gm.

Arsaminol 0.5 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.5 Gm.

Arsaminol 0.6 Gm. Tubes.—Each hermetically sealed tube contains arsaminol 0.6 Gm.

CHLORAMINE-T.—Sodium Paratoluenesulphochloramide. —$CH_3.C_6H_4.SO_2NaNCl+3H_2O$, 1:4.

Actions, Uses, Dosage, Physical and Chemical Properties.—See New and Nonofficial Remedies, 1918, p. 156.

Chloramine-T, *Monsanto*.—A brand of chloramine-T.

Manufactured by the Monsanto Chemical Works, St. Louis. No U. S. patent or trademark.

THE VENOPRESSOR MECHANISM

In order to enable the heart to distribute a suitable modicum of blood to the tissues and organs, a corresponding quantity must be delivered to the cardiac pump for circulation. However obvious this may be to the critical student of hemodynamics, it has not received the recognition that such a fundamental fact requires from the casual observer of circulatory phenomena. The important factors in the diastolic filling of the heart that limit the volume of blood circulated in any unit of time are the venous pressure and the volume of the venous return of blood. The needs of different parts of the body for blood vary enormously at different times. Rest and vigorous muscular activity represent, for example, extremes of condition that determine widely unlike demands for blood distribution by the heart. Correspondingly enormous variations in the volume of venous blood return required and provided occur. Accordingly there must be some mechanism, to quote a recent writer,[1] controlling the supply of blood from the veins to the heart and regulating the variations needed during rest and exercise. This mechanism must adjust the venous pressure to dilate the right heart during diastole, neither over nor underfilling the ventricle.

How is the advantageous control of this admittedly essential venopressor mechanism brought about? A few years ago when the peripheral modification of blood flow was believed to be associated solely with changes in the caliber of the arterial system, an active as contrasted with a merely passive change in size of the smaller efferent vessels, the venules, was scarcely taken into account as a vasomotor possibility. Vasomotor control was almost synonymous with regulation of the arterial side of the circulatory cycle. Today we must admit that the capillaries and venules also may participate more actively in a change in caliber that will modify the possibility of the blood flow through them.

Recent studies are beginning to indicate the probability—if, indeed, they do not clearly demonstrate—that both nervous and chemical factors may contribute to vascular relaxation and change in the capillary and venous regions. Hooker[2] has recently demonstrated how a rise of venous pressure may be obtained quite independently of arterial factors, through responses of the venopressor mechanism, particularly by directing nervous influences on it. Perhaps even more significant and novel are the contributions of Henderson and Harvey[1] from the physiologic laboratory of the Yale School of Medicine, which suggest that the venopressor mechanism consists essentially in the chemical influence, either directly or through a local nervous mechanism, on the caliber of the capillaries and especially of the small efferent vessels, the venules, exerted by the greater or less venosity of the blood in and flowing from the organs, especially the skeletal muscles. The greater the activity of the muscles, the more venous this blood. The efferent vessels are thus relaxed and the outflow from the capillaries into the venous system made easier. The volume of the venous return to the heart is increased, the venous pressure is raised and (within certain limits) the efficiency of the heart is increased. Thus the two extremes of high venous pressure on the one hand and abnormally low venous pressure on the other are induced, respectively, the former by muscular exertion with great carbon dioxid production and the latter by acapnia and related conditions.

The demonstration of such a venopressor mechanism distinct from the traditional vasomotor nervous regulation—a mechanism consisting of a peripheral chemical control, largely through variations in the carbon dioxid content of the venous blood, over the venous pressure and the volume of the venous return—is founded on recently reported experiments.[1] Thus Henderson and Harvey found that procedures which strongly influence vasomotor innervation cause on the whole decidedly greater alterations of arterial than of venous pressure, and the alterations of venous pressure are often only momentary and therefore largely indirect and secondary to redistribution of blood. On the other hand, admittedly chemical changes that have little or no effect on arterial pressure, other than an increased amplitude of pulse, cause an enormous rise of venous pressure. Thus another instance is added to the growing evidences for chemical regulation of vital functions—in this case factors in the circulation "acting as a powerful accessory to the vasomotor nervous system in accelerating the venous return, and regulated by chemical rather than by nervous influences." If shock involves a fall of arterial pressure due to decreased venous return to the heart, the possible importance of the phenomena just discussed must become obvious. But this is a province of perennial debate that we hesitate to enter.

PALEOPATHOLOGIC STUDIES

Paleopathology, as we have pointed out,[1] is a new word for a very old subject, which is only now beginning to attract the attention it deserves. All physicians interested in the scientific side of medicine, especially those who have professional and educational interests at heart, should be familiar with its recent progress. The term was originally proposed, we believe, by Ruffer in 1914, when, in the course of researches on ancient Egyptian mummies, he realized that the study of pathologic changes occurring in past ages ought to have a definite place of its own in medical science. Mummies have revealed the fact that pathology in its present form is as old as human history, and that bones particularly, but also arteries and other tissues, when preserved as the mummies have been, demonstrate that humanity has not changed in its pathologic reactions for fifty centuries at least. It is interesting to find arteriosclerosis affecting the Egyptians just as it does men of our time. It is illuminating to realize that in spite of the fact that the ancient Egyptians led lives of ease, had no tobacco, and did not overindulge in meat eating, their arteries degenerated practically in the same way as our own.

Keith,[2] in discussing the trephined skulls from the Neolithic graves in France, states that in one Neolithic sepulchral chamber accidentally discovered in 1908 on the side of a hill at Vendrest, about 60 miles east of Paris, remains of more than 120 individuals representing both sexes and all ages were found, and no less than eighty skulls had been trephined during life. Such skulls have been found elsewhere in France and also in England, some of them with more than one trephine opening. Manifestly, the operation was rather frequently done. The operations were performed not less than 4,000, and some of them perhaps 6,000 years ago, with stone instruments; for the use of metals had not as yet been learned. As the margins of the openings are healed over, the patients had recovered completely. It has been suggested that the operations may have been performed on patients suffering from various forms of insanity, with the idea of letting out a bad spirit. Something like this is needed to account for the frequency with which trephined skulls are found in certain places, and, if true, will afford a basis for some interesting reflections on insanity thus early in mankind.

The question of epidemics in the distant past may arise and find a more or less satisfactory answer in paleopathology. There seems no doubt now that tuberculosis can be traced in certain regulations of the Code of Hammurabi, about 2,000 B. C. Dr. John K. Mitchell (3d), at the Philadelphia museum, felt that he could trace definite signs of the occurrence of infantile paralysis in the mummy of a young prince of one of the early dynasties of Egypt, probably about 4,000 B. C. The presence of tsetse flies in the Oligocene of Colorado suggests the possibility of trypanosomiasis among the herds of the earliest animals in this country of which we know anything. It is possible that some of the huge animals of the early times, whose strength would seem to secure them a power of survival, disappeared not before the severity of changing climate or the attacks of smaller but more active animals, but before the insidious invasion of microorganisms, which literally swept them out of existence. Professor Conklin of Princeton, in his lectures on biology, reminds us that the great rule of history has been that "the mighty are put down from their seats, and those of low degree are exalted."

Paleopathology may very well prove capable of throwing light on practical problems of present day medicine, though of itself it is interesting because it extends the range of the history of medicine from that of human times into the very oldest periods. Physicians can scarcely help but realize how much of dignity is added to our everyday pathology, once we appreciate that pathologic changes similar to those that we study now can be found in the bones and other durable remains of old-time animals, literally thousands of generations ago and probably even hundreds of thousands of years before our era.

INSECT-BORNE DISEASES AND THE WAR

Owing to the transport of troops to and from almost all parts of the world, the war has provided a ready means of conveying diseases, hitherto unknown, to various countries. This has been the case especially with tropical diseases, which in the past three years have occurred with more or less frequency in temperate climates, in France and England, for example. In some features, the war has resembled the Crusades in that during its continuance there has been a constant stream of large groups of men traveling backward and forward from eastern Europe and Asia to western Europe. There has been an increasing ingress into France, and to a considerably less extent, into England, of troops from nearly every part of Africa and the Orient; therefore the parasitic diseases that have been introduced in this manner cannot fail to have infected some of our men, and unless precautions are taken may be a menace to our civilian population.

Some of the maladies prevalent in hot climates already have been shown to be spread chiefly or largely by insects, and, of course, it is more than likely that insects are factors in the transmission of the majority of these infections. Mosquitoes and biting flies are responsible for some of the most deadly diseases, as malaria, yellow fever and sleeping sickness, while the rat flea plays the most prominent part in the dissemination of plague. The mosquitoes *Stegomyia fasciata* and *Culex* and the sandfly *Phlebotomus perniciosus* are considered to be the vehicles whereby Mediterranean dengue is conveyed to man. Adrien[1] believes that the phlebotomus is the "carrier," mosquitoes acting only as possible transmitters. Cleland and Bradley,[2] describing an outbreak of dengue in Australia, give data that seem to show beyond a doubt that the virus of dengue in Australia is conveyed by *Stegomyia fasciata*, which undergoes some development in this insect. Indeed, according to these authors, the disease and its mode of transmission exhibit many points of resemblance to yellow fever. The body louse is rightly indicted as being largely concerned in the spread of typhus fever, and the same insect has been practically proved guilty of transmitting trench fever. In fact, this is apparently the important and common mode of transmission. Incidentally, it may be said that although the bedbug has been under suspicion for some time as an agent in the conveyance of certain infectious diseases, investigations undertaken thus far tend to clear it of the imputation.

[2] Keith, Arthur: The Antiquity of Man, Philadelphia, J. B. Lippincott Company, 1915.

The particular point which it is desired to emphasize is that the return of troops from Europe to this country is, to some extent, a source of danger to the general population. Diseases foreign to our shores may be brought into this country by returned soldiers, if great care is not taken, especially those introduced mainly by the agency of body lice. While it is obvious that with the cessation of hostilities the ridding of troops from body vermin can be considerably facilitated, the actual danger of spreading disease by lice may not be greatly minimized. Disinfection may not be so thoroughly carried out as in time of war, and it is by no means improbable that demobilized soldiers on their return to America may carry infected lice on their bodies or on their clothes. Moreover, there seems to be little doubt that on the American troops will fall the duty of performing some of the policing of Europe. They may be stationed in the Balkans, in parts of Russia and in the Central Empires, in some of which countries conditions favorable to the contraction of insect-borne diseases, and of lice-borne diseases in particular, exist. On the borders of Serbia it needs only a spark to start a conflagration of typhus fever, and the only methods of preventing such a calamity, in which, if extraordinary precautions are not taken, the troops might participate, are to exterminate the body lice so far as is possible. It must be borne in mind that in order to prevent typhus fever or trench fever, or, at any rate, to limit their spread among troops, the best efforts must be put forth to keep soldiers from infestation with lice. There is another point to which attention may be drawn: It is thought to be possible to disseminate trench fever by the agency of urine and sputum, both of which become infected and presumably may remain infected for a considerable length of time. Therefore it seems advisable that urine and sputum of returned soldiers who have been subjected to infestation by lice should be sterilized. If it may appear somewhat far fetched to suggest that troops returned from Europe may infect the civilian population with parasitic diseases, it remains to be said that parasitic diseases have occurred among the white population of France and England imported by troops from the Orient, Africa or eastern Europe. In existing circumstances, it is wise to err on the side of caution, and every conceivable step should be taken to protect the soldiers from infection by insect-borne diseases and to safeguard the inhabitants of this country from the spread of similar diseases introduced by the returned soldier.

SURVEY OF CRIPPLES IN CLEVELAND

One of the good results of the war has been a stimulation of interest in the physically handicapped, in cripples of whatever degree of incapacity. Systematic efforts are being made to devise apparatus, occupations and methods of training that will enable the cripple to remain or become self-supporting. One evidence of this interest is the report on the education and occupations of cripples based on a survey of cripples in Cleveland. It is compiled by the Welfare Federation of Cleveland and published by the Red Cross Institute for Crippled and Disabled Men of New York City. In spite of our boasted progress, public sentiment in most of our cities has become hardened to the spectacle of the lame beggar or the crippled shoestring merchant or lead-pencil vender. A survey, establishing the exact amount of dependency due to this cause, is a valuable contribution to our knowledge in a field in which accurate data are lacking. With the exception of the Massachusetts census report for 1905, little attention has been given to this subject, so that the Cleveland survey is not only the first census of the cripples of a city that has been taken but is also the most comprehensive and analytic study of its kind ever undertaken. A house-to-house canvass, involving visits to 150,000 families, revealed 4,186 persons physically defective, crippled or incapacitated to such an extent as to place them within the limits of the definition adopted by the committee. In a similar census in Birmingham, England, in 1911, the definition adopted was: "a person whose muscular movements are so far restricted by accident or disease as to affect his capacity for self-support." The Cleveland committee found it advisable to modify this double physical and economic qualification so as to make the census include all persons physically handicapped, without regard to their economic condition. Taking the estimated population of Cleveland for 1916 as 674,073, the estimated ratio of cripples is 6 cripples to each 1,000 inhabitants. This tallies very closely with the results of the Massachusetts census, which gave 5.7 per thousand. Of the 4,186 cripples found, 2,638 were male and 1,548 female. Grouped by ages, 936, or 22 per cent., were less than 15 years of age; 2,553, or 61 per cent., were between the ages of 15 and 60, and 697, or 17 per cent., were over 60 years of age. Two thousand and forty-six, or nearly one half of the total number, became crippled before they were 15 years of age; 1,820, or 43 per cent., became crippled during the priod of active working life, that is, between 15 and 60, while only 273, or 6 per cent., became crippled after the age of 60 years. Regarding the form and degree of incapacity, 735, or 17 per cent., lost arms or portions of arms; 2,404, or 58 per cent., lost legs; 332, or 8 per cent., lost one or both arms or one or both legs; 272, or 6 per cent., had deformity or paralysis of the body, and 443, or 11 per cent., disability of arms or legs, or of both arms and legs and of body. The causes of disability are: congenital, 301; occupational accidents, 468; other accidents, 1,323; infantile paralysis, 525; other diseases, 1,437; not stated, 132. Occupational accidents, most of which were preventable, and infantile paralysis, a preventable contagious disease, are together responsible for 993, or 25.72 per cent., while crippling due to accidents and diseases of all kinds amount to 3,753, or 89.65 per cent. Infantile paralysis alone is responsible for one eighth of all the cripples and for 41 per cent. of the crippled children. Tuberculosis caused 15 per cent. of the crippling among children.

---

[1] Adrien, Charles: Arch. de méd. et pharm. nav. **105**: 275 (April) 1918.

[2] Cleland, J. B., and Bradley, B.: J. Hyg. **16**: 317 (Jan.) 1918.

For obvious reasons, the percentage of illiterates was high. Three hundred and forty-seven under 9 years of age were not attending school; 282 cripples over 10 years of age were illiterate. The figures regarding employment are gratifying: Out of 3,250 persons over 15 years of age, 1,912, or 59 per cent., were employed in spite of the handicap of their physical condition, while 1,338, or 41 per cent., were not employed. Wages for crippled persons employed range from $6 to $50 a week, the largest number being in the $10 to $15 a week class; 1,743 are earning a living, and more than half of these are earning a living not only for themselves but also for others. Of those supported by other means than work, 1,034 out of the total of 1,418 are supported by their families, 136 by income, and 125 by relief agencies; fifty-six are in receipt of industrial pensions. Of 593 females at work, 400, or 67 per cent., are active housekeepers. Of the sixty occupations followed by four or more crippled men, the largest group were unskilled workmen or those doing work not dependent on muscular activity. The report, which contains many tables and much interesting data, as well as personal sketches and the histories of selected cases, concludes with recommendations for the reduction of crippling diseases and accidents and the better care of persons already disabled.

The survey and report form a most commendable piece of constructive work. Far too much of our public health energy heretofore has been expended in work that was largely sentimental and nonproductive. The first requisite for the improvement of any condition is an accurate knowledge of all the facts pertaining to that condition. In too many instances in the public health field, our knowledge is fragmentary, vague and unsystematic. The method that has produced results in scientific circles must be followed in the public health field: careful, painstaking, detailed study of small sections of the field, gradual extension of knowledge, and final grouping of all available data into a generalized whole. To this end, the Cleveland survey is a praiseworthy contribution.

Current Comment

OUR FOREIGN EXCHANGES IN 1918

Notwithstanding the censor and the U-boats, the foreign language exchanges have been received with great regularity so that the file for 1918 is complete to date for nearly all, and they have been duly indexed. They arrived sometimes far out of chronological order, but as months passed this condition righted itself. No Russian journals of any kind were received during 1918, and of course no journals from Germany or Austria. But the German language was represented, as the *Correspondenz-Blatt für Schweizer Aerzte*, of Basel, Switzerland, and one other of the three Swiss journals listed, and some of the five Japanese exchanges are published in German. The aspect of the French and Italian journals of 1918 with their blank or effaced advertising pages is of historical interest. The scarcity of paper is shown by the smaller number of pages and the quality of the paper. Italy seems to have suffered most in the latter respect; the four weeklies are printed on very poor paper. The *Riforma Medica* looks, indeed, as if it "had been through the war," as the large size of its page, 10 by 14 inches, and the consequent folding of the paper to mail it, give it a dilapidated air even when first received. The *Policlinico* in its compact 7 by 10 page keeps its shape perfectly, but a recent editorial in this important weekly stated that "paper which before the war cost 40 or 50 lire a hundredweight now costs from 350 to 400 lire, and is of such poor quality that in normal times we would not accept it as a gift." The journals of South and Central America, Mexico and the West Indies show no appreciable evidence of the scarcity of paper, although all our exchanges complain of the high price. The 1918 file is complete to date for our three Swedish exchanges, the one Norwegian monthly, the two Danish weeklies, and the four Portuguese journals from Brazil. Nine Italian journals are complete with the exception of one copy of the *Policlinico*. Two of the twenty-one French exchanges lack a few numbers, as also two of the eight exchanges from Spain and four of the twenty-eight received from South and Central America, Mexico and the West Indies. Thus only nineteen numbers failed to reach us of eighty-three foreign language exchanges, regularly indexed, while the greatest war in history was being waged, with diabolical efforts to arrest all ocean traffic, including the mails.

A HEALTH ALMANAC FOR MINERS

Some years ago a number of state health officials, impressed with the value of the old-fashioned almanac as a cherished and frequently consulted household guide, objected to the apparent monopoly of this medium by the "patent medicine" interests. They saw no reason why an almanac could not be made a messenger of health instead of an advance agent for somebody's green pills. Accordingly, health almanacs were issued by a number of our state health departments, apparently with good results. The Bureau of Mines of the Department of the Interior has followed the same plan in issuing Miners' Circular 24, a miners' safety and health almanac for 1919. It is published in cooperation with the United States Public Health Service. The usual and familiar monthly tables are interspersed with reading matter, offering good advice to the miner regarding his health and safety. The table of contents shows that a majority of the subjects are health topics, such as pneumonia, smallpox, drinking water, sore eyes in new-born babies, pellagra, flies, mosquitoes, garbage, typhoid, "patent medicines," and the care of the teeth. Other articles relate to safety, under such headings as responsibility of the miner, ten commandments to prevent accidents, mechanical safeguards, methods of making coal dust harmless, precautions in a gaseous mine, mine rescue apparatus, and explosives used in mining. The calendar, in place of the familiar historical events, contains a health or safety fact or warning for each day. The reading matter is attractively and interestingly written, and illustrations and diagrams abound. This effort to teach health and industrial safety to miners through an old and familiar medium is worthy of imitation in other occupations.

HEREDITARY TENDENCY TO FORM CERTAIN TUMORS

The part played by heredity in the incidence of a not inconsiderable number of diseases has come to be recognized as an indisputable factor in the study of their causation. The tendency to form vascular tumors of the skin and mucous membranes, pigmented patches in the skin, and polyadenomas, for example, is now believed to be a dominant trait, as the student of genetics terms it. Dr. Charles B. Davenport[1] of the Carnegie Institution's Station for Experimental Evolution believes that to this group of heredity belong also epidermolysis bullosa, angioneurotic edema, and persistent hereditary edema, and such skin diseases as psoriasis, porokeratosis and ichthyosis. Recently he has secured the statistical evidence which demontrates that the rather rare condition known as multiple neurofibromatosis represents a similar hereditary tendency. It is reported that despite the rarity of the malady there are many cases in the literature in which from two to six members of the family show some of the symptoms. From the fact that only blood relatives are affected, Davenport adds that the disease is not a communicable one, and it is equally certain that it is not induced by infection through the placenta. The two sexes are nearly equally apt to be affected—of 243 affected persons, 56.8 per cent. are males. The disease tends to recur without a break in the generations, and is equally apt to come down the male and the female line. Consequently it looks as though the hereditary factor in neurofibromatosis is a dominant one. Modern experimental studies on the spontaneous occurrence of tumors in laboratory animals have given much support to the prominence of the hereditary factor in the problem that they present. Davenport states that in not a few cases the removal of neurofibromas in man has been followed by the appearance of malignant growths at the same spot. As neurofibromas, which thus seem to be related to cancerous growths, have an inheritable basis, it is suggested that the alleged association of cancers in general with such a hereditary factor is further strengthened.

INDIANA GOVERNOR'S HEALTH RECOMMENDATIONS

It is to be expected that each year will show increased interest in constructive health legislation on the part of state executives. This naturally growing interest has been augmented by the prominence given to health questions through problems arising out of the war. It is not surprising, therefore, but rather an evidence of progress in conformity with the spirit of the times, that Governor Goodrich of Indiana should devote a considerable amount of space to health topics in his message to the General Assembly. "It is the first duty of the state," he says, "to do everything possible to conserve the health, the physical and moral well-being of our people. It has been demonstrated that our public health laws are inadequate to meet the situation. The revelations of the draft examinations are convincing. Not only has a large proportion of our young men been pronounced unfit for service and rejected on the initial examination, but as the further sifting process has been continued, it has been ascertained that at least one-third of the young men of the country were unfit for service. . . . Physical education is as necessary to the development of our young people as mental training. . . . Our educational system should be so organized as to provide for compulsory physical education of our young people." As a practical recommendation for better health conditions in the state, the governor indorses the movement for all-time health officials. This indorsement should be of great assistance to the state board of health in its efforts to secure whole-time town and county health officials. The governor also discusses the rural school question from a health standpoint, basing his recommendations on the surveys and reports made by the Federal Commissioner of Education and the National Education Association, in cooperation with the American Medical Association. While admitting a just pride in the work and accomplishment of the rural schools of Indiana, he urges on the legislature that much remains to be acomplished for the improvement of sanitary and health conditions among rural schoolchildren and recommends careful consideration of the problems involved. Governor Goodrich's message is a gratifying evidence of the growing interest taken in health problems by our most progressive state executives. With such a governor progress in health matters in Indiana should be rapid.

Association News

THE ATLANTIC CITY SESSION

Governmental Status Given the Victory Meeting Through Approval of the Secretary of War

As already announced, the annual session to be held next June will be a "victory" meeting. One of the special features will be the bringing together of medical representatives of the allied governments associated in the world war to plan for cooperative interallied study and research, to discuss methods for taking advantage of the advances in medical science that have developed because of the war, and to cement the bonds of an enduring friendship among medical men. The following correspondence relates to the subject:

Washington, D. C., Dec. 23, 1918.

My dear Mr. Secretary:

The annual meeting of the American Medical Association will be held at Atlantic City, N. J., from June 9 to 13, 1919. It has a membership of more than 80,000 physicians and surgeons. Approximately 40,000 of its members have served in the Medical Department of the Army during the world war. The annual meeting at Atlantic City will be called a victory meeting of the American Medical Association.

It is desired by the leading members of the medical profession of this country to make this victory meeting a notable one, and that representative medical men of all of the allied governments associated in the world war may be invited to attend the meeting for the purpose of conference on and compilation of the knowledge of medical science growing out of the war.

That these invitations to the foreign representatives may have something of an official character, it is requested that the invitations may be sent by the officers of the American Medical Association under the patronage of the Medical Department of the Army of the United States.

No expense to the United States government is implied in this suggestion. Attached hereto is a memorandum for your signature if the proposition meets your approval.

Very sincerely yours,
(Signed) M. W. Ireland,
Surgeon-General, U. S. Army.

To the Honorable Newton D. Baker,
Secretary of War.

Dec. 23, 1918.

The American Medical Association is authorized, under the patronage of the Medical Department of the Army of the United States, to invite medical representatives of the allied governments associated in the world war to the annual victory meeting to be held at Atlantic City, New Jersey, from June 9 to 13, 1919.

(Signed) Newton D. Baker.

The approval of the Secretary of War gives the session of the Association a governmental status. The Board of Trustees has appointed and empowered the following committee to act for the Association in inviting these delegates: Arthur Dean Bevan, President; Alexander Lambert, President-Elect; Alexander R. Craig, Secretary; Merritte W. Ireland, Surgeon-General of the U. S. Army; William C. Braisted, Surgeon-General of the U. S. Navy; William H. Welsh and William J. Mayo, Ex-Presidents; and the following members of the Board of Trustees: Philip Marvel, Wendell C. Phillips, D. Chester Brown and Frank Billings, the last mentioned being chairman of the committee.

Alexander R. Craig, Secretary,
American Medical Association.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending January 10, there were in the Medical Reserve Corps 626 officers. This personnel includes forty-eighty majors, eighty-seven captains and 491 lieutenants. There were in the regular Medical Corps 26,017, a decrease of 1,597 since the previous week. Discharges to date include 8,194 officers.

Awards for Bravery

The Commander in Chief, in the name of the President, has awarded the Distinguished Service Cross to the following named officers of the medical department:

Lieut. ROBERT H. MURDOCH, deceased, Medical Corps, 47th Infantry. For repeated acts of extraordinary heroism in action at Sergy, France, July 29-31, 1917; and at St. Thibaut, France, August 6-12, 1918. Accompanying his battalion in the attack on Sergy, Lieutenant Murdoch advanced for more than a mile under heavy shell fire, and as soon as the southern half of the town had been taken he established his dressing station, maintaining it during the three days of fighting under constant and severe bombardment. When his battalion went into action at St. Thibaut this faithful officer again displayed heroic devotion to duty by working in his dressing station under the most trying conditions for six days while the town was bombarded with gas and high explosive shells.

Major JACKSON S. LAWRENCE, Medical Corps, 368th Infantry: For extraordinary heroism in action at Binarville, France, Sept. 30, 1918. Major Lawrence, with two soldiers, voluntarily left shelter and crossed an open space 50 yards wide, swept by shell and machine gun fire, to rescue a wounded soldier whom they carried to a place of safety.

Lieut. JOHN F. DOUDNA, Lake City, Mich., Medical Corps, 362d Infantry. For extraordinary heroism in action. This officer was under constant shell fire with his battalion for 17 days, and though he had been painfully wounded by a machine gun bullet, he remained at his post rendering first aid to the wounded night and day, performing the duties of two other medical officers, who had been incapacitated, in addition to his own. Lieutenant Doudna's utter disregard for personal danger and complete devotion to duty made possible the rapid evacuation of the wounded, thus materially keeping up the morale of the combat troops and alleviating the suffering of the wounded.

Lieut. ROSS E. WEAVER, Medical Corps, 102d Infantry. For extraordinary heroism in action at Marcheville, Sept. 26, 1918. Lieutenant Weaver showed complete disregard of personal safety by remaining with the foremost elements and administering aid to the wounded throughout the day under constant artillery bombardment and direct machine gun and rifle fire from the enemy.

Lieut. CHARLES W. COMFORT, New Haven, Medical Corps, 102d Infantry. For extraordinary heroism in action at Seicheprey, France, April 20, 1918. Lieutenant Comfort administered first aid for 36 hours, without rest or relief, to numerous wounded in the open, almost constantly under heavy artillery fire, and assisted in their evacuation, thereby setting an example of heroic performance of his duties under the most trying circumstances. A bronze oak leaf is awarded to Lieutenant Comfort for the following act of extraordinary heroism: On Sept. 26, 1918, near Marcheville, France, he displayed the highest courage and devotion to duty, being continually present on the front line administering first aid to the wounded under violent artillery and machine gun fire.

Lieut. JOSEPH H. DUNN, 101st Sanitary Train. For extraordinary heroism in action near Marcheville, France, Sept. 25-26, 1918. Lieutenant Dunn assisted in establishing and maintaining an ambulance dressing station in an advanced position, where he labored heroically dressing and evacuating the wounded in full view of the enemy, under constant heavy bombardment by the enemy.

Lieut. HENRY E. CHRISTIANSEN, Chicago, Ill., Medical Corps, 101st Ambulance Company. For extraordinary heroism in action at Saulx, France, Sept. 25-26, 1918. Lieutenant Christiansen established and operated a dressing station in an advanced position under constant heavy bombardment by the enemy. When word was received that our troops were withdrawing and permission had been given to move his station to a safer position he declined to withdraw, but continued his work of ministering to the wounded.

Specialized Treatment for the Wounded

In order to furnish specialized treatment for the wounded Surgeon-General Ireland has issued instructions to commanders of hospitals that special care be taken to provide specialists for treatment of various types of wounds. In addition arrangements have been made for the sending of certain classes of patients to specific hospitals where special facilities for treatment are provided. The following items are taken from a list recently published:

Blindness (or near blindness).—General Hospital No. 7, Roland Park, Md.

Deafness (total or near total).—General Hospital No. 11, Cape May, N. J.

Insane (officers).—General Hospital No. 1, Williamsbridge, N. Y.

Insane (officers and enlisted men).—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 4, Fort Porter, N. Y.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 13, Dansville, N. Y. (no violent, suicidal or homicidal cases); General Hospital No. 25, Fort Benjamin Harrison, Ind.; General Hospital No. 26, Fort Des Moines, Iowa;

General Hospital No. 28, Fort Sheridan, Ill.; General Hospital No. 34, East Norfolk (Pondville), Mass.; base hospital, Fort Sam Houston, Tex.

Maxillofacial (injuries of face and jaw).—Walter Reed General Hospital, Takoma Park, D. C.; General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 11, Cape May, N. J.

Speech defects (which are not neurotic).—General Hospital No. 11, Cape May, N. J.

Neuroses (functional) drug addicts and inebriates.—General Hospital No. 30, Plattsburg Barracks, N. Y.

Epileptics and mental defectives.—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 1, Williamsbridge, N. Y.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 25, Fort Benjamin Harrison, Ind.; General Hospital No. 26, Fort Des Moines, Iowa; General Hospital No. 28, Fort Sheridan, Ill.; General Hospital No. 29, Fort Snelling, Minn.; base hospital, Fort Sam Houston, Tex.

Tuberculosis, pulmonary.—General hospital, Fort Bayard, N. M.; General Hospital No. 8, Otisville, N. Y.; General Hospital No. 16, New Haven, Conn.; General Hospital No. 17, Markleton, Pa.; General Hospital No. 18, Richland (Waynesville), N. C.; General Hospital No. 19, Oteen (Biltmore), N. C.; General Hospital No. 20, Whipple Barracks, Ariz.; General Hospital No. 21, Denver.

Amputations (lower extremities only).—General Hospital No. 3, Colonia (Rahway), N. J.

Amputations (for amputations fingers and toes, see General surgery).—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 10, Boston; General Hospital No. 26, Fort Des Moines, Iowa; General Hospital No. 29, Fort Snelling, Minn.

Arthritis, chronic (nontraumatic).—Letterman General Hospital, San Francisco; Walter Reed General Hospital, Takoma Park, D. C.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 9 (ambulant cases only), Lakewood, N. J.; General Hospital No. 10, Boston; General Hospital No. 26, Fort Des Moines, Iowa; General Hospital No. 28, Fort Sheridan, Ill.

Wounds or injuries of the skull or brain (including traumatic epilepsy) and injuries or diseases requiring surgical treatment of importance of eye, ear, nose and throat.—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 11, Cape May, N. J.

Wounds or injuries of the spinal cord and organic disease of nervous system.—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 3, Colonia (Rahway) N. J.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 11, Cape May, N. J.; General Hospital No. 28, Fort Sheridan, Ill.; General Hospital No. 29, Fort Snelling, Minn.

Peripheral nerve injuries and paralyses (including healed or unhealed wounds, with or without fracture).—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 1, Williamsbridge, N. Y.; General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 3, Colonia (Rahway), N. J.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 11, Cape May, N. J.; General Hospital No. 26, Fort Des Moines, Iowa; General Hospital No. 28, Fort Sheridan, Ill.; General Hospital No. 29, Fort Snelling, Minn.

Orthopedic cases.—(1) Deformities of extremities due to or associated with contractures of muscles, ligaments and tendons; (2) derangements and disabilities of joints, including articular fractures; (3) deformities and disabilities of the feet; (4) cases requiring tendon transplantation.—Walter Reed General Hospital, Takoma Park, D. C.; Letterman General Hospital, San Francisco; General Hospital No. 1, Williamsbridge, N. Y.; General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 3, Colonia (Rahway), N. J.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 9, Lakewood, N. J. (ambulant cases only); General Hospital No. 10, Boston; General Hospital No. 26, Fort Des Moines, Iowa; General Hospital No. 28, Fort Sheridan, Ill.; General Hospital No. 29, Fort Snelling, Minn.; General Hospital No. 36, Detroit; General Hospital No. 39, Long Beach, Long Island, N. Y.

General medical cases and general surgical cases will be treated in all the cantonment base hospitals and in most of the general hospitals.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

Virginia

To Camp Lee, Va., base hospital, from Rockefeller Institute, Lieut. C. H. IDEN, Berryville.

To Richmond, Va., from Camp Dix, Lieut. R. C. HOCKER, Richmond.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to his proper station*, from Biltmore, N. C., Capt. J. T. BUXTON, Newport News.

To West Point, N. Y., from Fort Oglethorpe, Lieut. W. H. Re MINE, Lodi.

Washington

To Camp Lewis, Wash., base hospital, from Camp Dodge, L. B. BALDWIN, Seattle.

To Vancouver Barracks, Wash., from Southern Department, Capt. J. B. BLAIR, Vancouver.

The following order has been revoked: *To Fort Monroe, Va.*, from Camp Crane, C. R. McCREARY, Tacoma.

West Virginia

To Camp Meade, Md., base hospital, from Detroit, Major H. D. HATFIELD, Huntington.

Wisconsin

To Camp Jackson, S. C., Emerson Field, from Americus, Ga., Capt. J. J. FRANCE, Milwaukee.

To Colonia, N. J., from Walter Reed General Hospital, Capt. J. C. ELSON, Madison.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Upton, N. Y.*, base hospital, from Camp Pike, Lieut. A. YAFFE, Milwaukee.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Sen. Surg. G. M. MAGRUDER, rejoin station at Tacoma, Wash., and proceed to Portland, Ore., to effect transfer of property at those stations.

Surg. B. J. LLOYD, granted three months' leave of absence from Jan. 2, 1919, with permission to proceed beyond the seas.

Passed Asst. Surg. J. A. WATKINS, granted two months' leave of absence on account of sickness with permission *to proceed beyond the seas.*

Passed Asst. Surg. H. C. CODY, proceed to Washington, D. C., for duty in epidemiologic investigations of influenza. Relieved at New London, Conn.

Asst. Surg. J. W. MOUNTIN, relieved at Waco, Texas; proceed to Marine Hospital, Chelsea, Mass.

Acting Asst. Surg. H. E. HENRY, relieved at Fort Worth, Texas; proceed to San Antonio, Texas, for duty.

Acting Asst. Surg. W. E. REASNER, proceed to necessary places in the State of Mississippi for duty in connection with the control of influenza.

Scien. Asst. L. L. LEE, relieved from duty in the District of Columbia, *proceed to Chester, Pa.*, for duty.

Scien. Asst. E. N. RILEY, proceed to Philadelphia, Pa., for duty in field investigations of industrial sanitation.

Resignation of Passed Asst. Surg. H. M. THOMETZ accepted by direction of the President, effective March 16, 1919.

Resignation of Asst. Surg. JOHN S. RUOFF accepted by direction of the President, effective March 19, 1919.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Library Given to Hospital.—Dr. Edmund W. Weis, Ottawa, who was recently appointed head of the hygienic institute, LaSalle, has donated his entire medical library to the Ryburn Memorial Hospital, Ottawa.

Officers Returned from France.—Lieut.-Col. Frederick A. Besley, M. C., U. S. Army, has returned to Chicago, and will go for a short vacation to California.——Lieut.-Col. Milton Mandel, M. C., U. S. Army, who went abroad as chief of the medical staff of Base Hospital No. 12, has returned to Chicago.

Proposed Change in Health Law.—The state department of public health is seeking the passage of an act providing for the appointment of a full-time health officer in each of the 102 counties of the state. An effort will also be made to modernize the relation of the state to the state's wards, and to provide physical rehabilitation of the state institutions on the business basis.

New Officers.—At the annual meeting of the Madison County Medical Society and the Madison County Anti-Tuberculosis Association, held in Edwardsville, January 4, Dr. Charles R. Kiser, Madison, was elected president; Dr. Frank O. Johnson, Granite City, vice president; Dr. Edward W. Fiegenbaum, Edwardsville, secretary; Dr. Joseph A. Hirsch, treasurer, and Dr. M. William Harrison, Collinsville, medical director of the tuberculosis association.

Development of Public Charities.—Charles H. Thorne, director of public welfare, has recommended that five new state institutions be established: an institution for feebleminded near Chicago; a state sanatorium for women; a state farm for male misdemeanants; a surgical institution for children, and educational hospitals to perfect the training service. The appropriation required for the establishment of these institutions aggregates more than $1,500,000.

Chicago

Well Known Masseur Dies.—Hugo Ad Oldenborg, one of the first Swedish masseurs to come to this city, a man of exceptional ability and well esteemed by the medical profession of Chicago, assistant professor of kinesitherapy in Rush Medical College, secretary for many years of the Scandinavian Medical Society, died at his home, January 11.

Opium in Influenza Prescriptions.—The health department of Chicago has completed a survey of drug stores which has shown that during the height of the influenza epidemic, physicians made widespread use of medicine containing habit-forming drugs. Between Oct. 1 and Nov. 1, 1918, the survey shows that 741,825 prescriptions had been filled in 946 drug stores in Chicago. Of these 441,641 were for influenza and pneumonia, and of the later 104,010 were found to contain narcotics, either opium, opium derivatives, cocain or chloral.

INDIANA

Deaths Exceed Births.—In Huntington, according to figures made public by the secretary of the city board of health during December, 1918, there were ten more deaths than births. The returns usually show about two births for each death. There were 29 births and 39 deaths. Of the deaths 23 were caused by influenza, 15 from pneumonia following or accompanying the influenza and eight were from other complications of influenza. Influenza deaths in the city were 3 in October, 8 in November and 23 in December.

Orphans Made by the Epidemic.—According to figures given out by the statistician of the state health department, influenza and pneumonia caused 6,011 deaths during the three months ending December 1. In September there were only 191 deaths from these causes, but in October there were 3,291, and in November 2,529. During the period named there were 2,773 deaths of married persons from the epidemic, and allowing an average of two children for each married person this would indicate that the disease made 5,546 orphans.

KANSAS

Personal.—Dr. George M. Gray, Kansas City, who has been acting as medical aide on the governor's staff, has resigned.

Full-Time Health Officer for Wichita.—In the 1919 budget for Wichita, provision is made for a full-time city physician at a salary of $3,000 a year. He will devote his entire time to the service of the city, including the maintenance of a free clinic.

New Officers.—At the annual meeting of the Shawnee County Medical Society, held in Topeka, January 6, Dr. Forrest L. Loveland was elected president; Dr. William M. Mills, vice president; Dr. Homer A. Alexander, secretary, and Dr. Lewis H. Munn, treasurer.

MARYLAND

Dr. Thayer Returns from France.—Brig-Gen. William S. Thayer, Baltimore, who has been serving in France, arrived at Newport News, Va., January 9, and has proceeded to report to Washington, D. C.

Annual Dinner of Health Department.—At the annual dinner given by the medical men of the Baltimore City Health Department in honor of Dr. John D. Blake, Baltimore, commissioner of health, addresses were made by Drs. John F. Hogan, William T. Howard, Bernard J. Wess, John W. France and Harry L. Kolseth, all of Baltimore. A round table discussion of suggestions for improvement of conditions in various city wards closed the program.

Personal.—Major Thomas R. Chambers, Baltimore, who has been stationed for the past nine months in France as a member of the Surgical Operating Squad, has arrived in Baltimore with orders to report to Camp Dix, N. J. Major Chambers was a member of the First Army Division while in France.——Dr. Charles A. Waters has returned to Baltimore from Camp Greenleaf, Ga., where he had been stationed for the past three months after returning from overseas service as a member of the Johns Hopkins Unit.

Health Department Denies "Flu" Report.—Dr. William T. Howard, Baltimore, assistant commissioner of health, has written to Dr. William H. Davis, chief statistician of the United States Bureau of Census, correcting a statement sent out from Washington that Baltimore had the highest death rate last year of any large city in the country. This city was credited with 15,999 deaths, or a mortality of 26.8 per thousand of population. According to the records of the health department, there were 15,120 deaths in the city in 1918, or fewer by 879 than the number given in a bulletin of the census bureau. Dr. Howard figures, therefore, that the city's annual death rate per thousand of population was 25.2. Furthermore, he corrected a published statement that Baltimore led forty-six large cities in the number of deaths from influenza during the epidemic. Philadelphia led these cities in deaths from influenza, with 7.4 per thousand of population. Pittsburgh came next with 6.8 per thousand, and Baltimore was third, with 6.5 per thousand. The influenza death rate in Boston was 5.5, while in Washington it was 5 per thousand. In Baltimore during the epidemic 1,624 persons died from influenza and 2,388 from pneumonia, which was epidemic at the same time. In Philadelphia there were 8,080 deaths from influenza and 5,295 from pneumonia. Pittsburgh had 1,989 deaths from influenza and 2,410 from pneumonia. In Boston there were 3,689 deaths from influenza and 1,099 from pneumonia.

MASSACHUSETTS

Beland to Speak in Worcester.—It is announced that Hon. Dr. Henri S. Beland, M.P., St. Joseph de Beauce, Que., who was a prisoner in Germany for three years, will speak in Worcester, January 26.

Personal.—Dr. William E. Chenery, professor of laryngology in Tufts Medical School, Boston, has been elected a member of the corporation of Boston University.——Drs. Clement H. Hollowell and Richard E. Winslow, Norwood, who were arraigned before the district court, Deadham, December 20, for alleged failure to report influenza cases, pleaded guilty and their cases were placed on file.——Dr. George Klein, Norwood, charged with having failed to report influenza cases, was found not guilty.

Sanatorium Enlarged.—The Central Sanatorium of New England, formerly the Crane Sanatorium, Rutland, is being enlarged so that it may care for a number of discharged soldiers and sailors in addition to the added number of civilian patients. The new sanatorium will be in accordance with the comprehensive plan to care eventually for hundreds or even thousands of patients suffering from tuberculosis. It is planned to provide occupational buildings for those patients whose condition allows them to be profitably employed.

Reprints on Diet and Child Welfare.—The Massachusetts State Board of Health has prepared in separate form a number of reprints of articles appearing in *The Commonhealth*, the monthly journal of the board, on dietary and other subjects, especially with reference to children, and also an outline for a course on child welfare. Among the subjects are "Food for the Child," "Energy-Producing Foods" and "Certain Dietary Essentials." These pamphlets are for general distribution, and are interesting contributions to the various subjects.

Influenza in Fall River.—The *Monthly Bulletin* of the board of health of Fall River for October, 1918, says of the epidemic of influenza: "That the disease was brought into this city through the medium of the members of the Army and Navy service of the United States is clearly shown by our records. Of the first cases reported, fourteen are classified as home on furlough or having been in the service as follows, and others reported were shown to have been visiting in some of these families: 1 from Quincy Shipyard; 1 from Newport Torpedo Station (yeowoman); 1 from Camp Upton, N. Y.; 1 from Newport Training Station; 1 from Newport (soldiers); 1 from Boston aviation service (British); 5 from Boston Navy Yard. In view of the subsequent suffering and death experienced during this epidemic it is to be regretted that the quarantine afterwards placed on all camps, forts and cantonments because of this disease was not recognized as necessary and put into effect before it obtained a foothold in Fall River."

NEBRASKA

Personal.—Dr. Clifford W. Waldon has been appointed city physician of Beatrice, to succeed Dr. G. L. Roe, who has resigned.

Hospital Notes.—A movement has been inaugurated at Kearney for the erection of a large hospital, the building to cost about $100,000. It is understood that there is already $50,000 for the project.——Work is progressing rapidly on the new Lutheran Hospital, Beatrice. It is believed the building will be ready for occupancy by June. When completed the hospital will be able to care for 100 patients.

Smallpox.—City Health Commissioner Ernest T. Manning of Omaha says the smallpox record of that city for 1918 is a disgrace. In a comparative statement of infectious diseases for the year he shows that there were 1,009 cases of smallpox, 651 cases of measles, 427 of diphtheria and 412 of scarlet fever. This preponderance of smallpox cases, he says, is due to lack of vaccination, which should be made compulsory.

NEW HAMPSHIRE

State Health Meeting.—A meeting of the health officers of the cities of the state was held in the Representatives' Hall in the State House, Concord, January 17 and 18. After-war health problems, school hygiene, influenza, venereal disease control and tuberculosis were the chief topics of discussion.

State Antituberculosis Society.—The annual meeting of directors of the New Hampshire Society for the Prevention of Tuberculosis was held in Manchester, recently and Dr. Clarence O. Coburn, Manchester, was elected president; Dr. Herbert L. Smith, Nashua, honorary vice president; Dr. Robert B. Kerr, Pembroke, executive secretary, and Drs. George H. Clarke, Concord; Forrest L. Keay, Rochester; Robert B. Kerr, Pembroke; Frank E. Kittredge, Nashua; William E. Lawrence, North Haverhill; Elmer M. Miller, Woodsville; George P. Morgan, Dover; John H. Neal, Portsmouth; Herbert L. Smith, Nashua; Ellen A. Wallace, Manchester; Charles A. Weaver, New Boston; John M. Wise, Glencliff, Charles Duncan, Concord, and Frederick P. Scribner, Manchester, were elected members of the board of directors.

NEW JERSEY

Tuberculosis Survey.—The health authorities of Atlantic City have arranged to have a tuberculosis survey made in the city, having especially in view the detection in their incipiency of cases of tuberculosis following attacks of influenza. A careful inspection of every recovered victim will be made and those showing signs of tuberculosis will be advised as to the proper course to pursue for their own protection as well as that of their families. It is within the discretion of the health department to order the isolation of patients when it is necessary for the safety of the public. Patients may be ordered to the county camp at Pine Rest.

Personal.—Dr. John A. Beck, Gloucester City, who resigned his position as city physician and health inspector to enter the Army, has been discharged and has returned home.——Dr. Henry B. Dunham, for ten years assistant superintendent and examining physician of New Jersey State Sanatorium for Tuberculosis, Glen Gardner, has been selected as superintendent of the Essex County Hospital, Soho, and Essex Mountain Sanatorium, Verona.——Dr. George W. Endicott, Plainfield, who has been seriously ill at his home, is reported to be improving.——Dr. and Mrs. Thomas H. Tomlinson, Plainfield, celebrated their fiftieth wedding anniversary, December 30.——Dr. J. Alan Maclay has been appointed a member of the board of health of Paterson.

NEW YORK

Officers of Mount Sinai Unit Return from France.—Lieut.-Col. Howard Lilienthal, M. C., U. S. Army, who has been in command of Army Base Hospital No. 3, near Bordeaux, arrived at Newport News, January 4.——Major Edwin Beer of the Mount Sinai unit has also returned home.

Personal.—Dr. Addison T. Halstead, Rushville, has been appointed deputy drug commissioner of the state, with headquarters in Albany.——Dr. Otis Z. Bouton, Fultonville, has been appointed coroner for Montgomery County to fill the unexpired term of the late Capt. Stephen J. H. Reed, Fultonville.——The City Club of Yonkers will tender a testimonial dinner to Dr. Nathan A. Warren, in recognition of the completion of seventeen years of service as president of the club.

Health Insurance Measures.—The first bill for 1919 to be introduced into the New York State Senate was one providing for the reorganization of the New York State Health Department which was submitted by Senator Ross Graves of Buffalo. This bill was introduced at the request of the Associated Manufacturers and Merchants of the state and is regarded in some quarters as a check to the propaganda for compulsory health insurance, though its sponsors deny this and state that the bill stands squarely on its own merits. The bill provides for an organized system of sickness prevention and carries an appropriation of $2,250,000. It is not expected that the bill will be passed at the present time, but it is regarded as a start in the right direction. January 8, a health insurance bill was introduced into the lower house by Assemblyman Joseph Steinberg of the Fifteenth Manhattan District. This bill provides for a system of mutual health insurance funds under the supervision of the Industrial Commission. It aims to supplement the inadequacies of the present Workmen's Compensation Law and provides for maternity benefits. The costs of the insurance are to be borne one half by the employer and one half by the employee. In cases in which the earnings of the employee are less than $9 a week and more than $5 they are to be borne three quarters by the employer and one quarter by the employee. The bill not only provides for health insurance, but also for prevention of disease by lessons in hygiene. An appropriation for this purpose is to be made with the consent of the Industrial Commission. Governor Smith is said to be ardently in favor of the bill and public sentiment is also supporting the measure.

New York City

Harvey Society Lecture.—The third lecture of the Harvey Society series will be delivered at the New York Academy of Medicine, Saturday, Jan. 25, 1919, at 8:30 o'clock, by Major R. M. Yerkes on "Psychological Examination of the Soldier."

Farm Given Medical College.—The Long Island College Hospital has been given a farm for keeping animals used in research, by an anonymous benefactor. Experimental work has already been begun on fowl influenza, diphtheria and chickenpox.

Personal.—Dr. Simon Flexner, director of laboratories of the Rockefeller Institute for Medical Research, has been elected a corresponding member of the Societé Médicale des Hôpitaux de Paris, and has had the title of Officier de la Legion d'Honneur conferred on him by the French government.

Physicians' Association Election.—At the annual meeting of the New York Physicians' Association the following officers were elected: president, Dr. Israel Grushlaw; vice presidents, Drs. James Morley Hitzrot and Samuel Kleinberg; secretary, Dr. Morris Grossman, and treasurer, Dr. Alfred M. Hellman. At the next meeting to be held at the Chemist's Club, January 23, Dr. Solis Cohen, Philadelphia, will read a paper entitled "Lessons from the Two Grippe Pandemics."

OREGON

New Officers.—At the annual meeting of the Portland City and County Medical Society, December 18, the following officers were elected: president, Dr. Charles J. Smith; vice president, Dr. Chester C. Moore; secretary, Dr. Andrew J. Browning, and treasurer, Dr. Katherine C. Manion.

Merging of Health Agencies Urged.—The State Consolidation Commission is recommending the creation of an office of director of public health and the consolidation of the present health agencies with the department. The recommendations made are ten in number, and are as follows:

First.—Creation of the office of director of public health, who shall be appointed by the governor, and be the executive health officer of the state.

Second.—Creation of an advisory nonexecutive public health council of seven members, appointed by the governor, and of which the health officer shall be ex-officio chairman.

Third.—That the Oregon Social Hygiene Society assume charge of the division of venereal diseases under that director.

Fourth.—That the Oregon Tuberculosis Society be authorized to assume charge of the tuberculosis division.

Fifth.—That the child welfare commission be given charge of the child welfare division.

Sixth.—That a deputy health officer be put in charge of the bureau of medical registration and licensure.

Seventh.—Consolidation of the laboratories of the state health department, the dairy and food commissioner, medical school of the University of Oregon, Multnomah county, and the city of Portland.

Eighth.—That a deputy appointed by the director be given direction of the bureau of food and dairy products.

Ninth.—An annual fee to be paid to the state by all licensed members of the health professions.

Tenth.—That all funds appropriated for health work be put under the jurisdiction of the director of public health, and by him apportioned among the various bureaus in his department.

PENNSYLVANIA

Philadelphia

Motion Pictures Aid Clinic.—Teaching surgery and medicine with the aid of motion pictures was demonstrated to the county medical society in Scottish Rite Hall, January 9, by Col. William O. Owen, M. C., U. S. Army, curator of the Army Medical Museum at Washington, who showed several of his "animated charts."

Women Interns for Hospital.—Beginning June 1 and for the first time in the history of the University of Pennsylvania, women physicians will be accepted as interns in the University Hospital. The only restrictions being that there shall be but two women physician interns at one time and that both shall be medical graduates of the University of Pennsylvania.

Influenza Survey Begins.—January 13, members of the Emergency Aid will begin a survey of the homes of the 4,000 women and children who suffered from the influenza last autumn to determine whether they are still in need of attention. This data will then be turned over to the Visiting Nurses' Society.——Influenza during the week ended January 9 had increased, 383 new cases having been recorded.

Social Education Conference.—A social education conference under the auspices of Department No. 10, Health Recreation, Women's Division, Council of National Defense and Women's Section Social Hygiene Division, Commission on Training Camp Activities of the War Department, was held at the Ritz Carlton Hotel, January 6 and 7. Among the speakers were Dr. Wilmer Krusen, director of public health and charities, Dr. Josephine H. Kenyon and Dr. Ellen C. Potter.

Personal.—Lieut. William H. Walsh, M. R. C., has just been made general medical inspector of the Children's Hospital, to be established near Mons, Belgium.——Capt. Frederick S. Baldi, M. R. C., who was attached to the Marine Aviation Corps and the Bombing Squadron, actively engaged around Dunkirk, has returned to this city.——Dr. Elwood L. Drake, Bridesburg, is in a serious condition as the result of injuries sustained by being thrown from his automobile in a collision, January 4.

SOUTH CAROLINA

Influenza.—The report of the officer of the Public Health Service sent to cooperate with the state health authorities in carrying out measures in the epidemic of influenza from September 21 to the first of the year indicates that about 10 per cent. of the entire population of the state suffered from the disease. The number of deaths was said to be about 5,000.

VIRGINIA

State Board Can Supply Physicians.—Dr. Ennion G. Williams, Richmond, state health commissioner, announces that the state board of health is now able to aid communities in need of physicians, since many physicians are now being separated from the Army.

Personal.—Dr. Roy K. Flannagan, city health officer of Richmond, has resigned, the resignation taking effect January 15. Dr. Flannagan has been offered the position of representative of the International Health Board for Virginia.——Dr. Thompson F. Wickliffe has succeeded Dr. James S. Mitchener, Kingston, resigned, as health officer of Lenoir County.

WYOMING

Influenza.—January 1, it was reported that there were on the previous day 300 cases of influenza in Jackson's Hole and that there had been five deaths during the preceding twenty-four hours. Dr. Charles W. Huff, the only physician in the valley was still confined to his home with the disease, and there were several other cases in his family.

CANADA

Influenza Expedition.—A dog team expedition has left Dawson, Yukon, on a trip of 500 miles, with supplies, medicines and masks for combating influenza among the Indians and Eskimos in that remote region. It was dispatched by the Commissioner of Indian Affairs, Ottawa, Canada.

New Hospital for Orillia.—Orillia, Ont., wants to have a new hospital as a memorial to soldiers. Already $60,000 has been raised by private subscription. Altogether $100,000 is required for the purpose; and recently a deputation waited on the Ontario government officials in Toronto to seek provincial assistance. Any soldiers who enlisted from Orillia, or who ever lived there, shall be given free surgical and medical assistance and hospital treatment as long as he lives.

Public Health News.—During the past three months influenza and pneumonia were responsible for 7,158 lives in the province of Ontario. The death rate was the highest in October when 3,105 succumbed to the malady.——There was an alarming increase of the number of cases of venereal diseases in Ontario in December as compared with November: syphilis, December, 64; November, 17; gonorrhea, December, 110; November, 75; chancroid, December, 4; November, 2. One death resulted from syphilis.——In Toronto the number of deaths in 1918 exceeded those of 1917 by 2,009—the total for the former year being 7,060 and for the latter, 5,597. The deaths from influenza and pneumonia numbered 2,067.——Brantford, Ont., will appoint a whole-time officer of health and a pathologist.

Mental Disease Great Menace.—In the Convocation Hall of the University of Toronto, Major Frankwood E. Williams, New York City, M. C., U. S. Army, recently gave an address under the auspices of the Canadian National Committee for Mental Hygiene. He doubted if many had a true conception of the problem presented by mental diseases. He gave figures for New York state and Massachusetts showing that 6,000 new cases enter the hospitals in the former every year and 3,000 every year in the latter. He considered prevention rather than cure the essential way to handle the problem. The United States Army officers have learned from Canada and Great Britain that mental diseases and nervous diseases present a large problem in all armies. The problem must be tackled on the ground of prevention if they wished to get at the root of the matter, and the persons with mental or nervous diseases should be studied as individuals and not as criminals. When they were understood, protected and advised they could get along on their own level in any community.

Personal.—Captain Greenlees and Lieut. John Stenhouse, Toronto, have been transferred to the Ontario Military Hospital, Coburg, Ont.——Surg.-Gen. G. A. Sterling Ryerson, Toronto, has resumed practice in diseases of the eye, after four years in Canadian Red Cross work—a society of which he is the founder in Canada and a past president. During the course of his work he has visited France and England, Quebec and Vancouver, Los Angeles, southern California and Sitka, Alaska. He also spoke in several points in the Eastern states.——Lieut.-Col. Charles S. McVicar, Toronto, is mentioned for the position of commanding officer for the Central Orthopedic Military Hospital.——Col. P. Walter H. McKeown, O. C., Brighton Military Hospital, England, is expected to return to Toronto in March.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

For the establishment of a home for convalescents at her residence in Payne Township, Chester County, Pa., including a large park, $250,000 by the will of Mrs. Florence Hatfield.

Mt. Sinai Hospital, Chicago, $25,000 as the result of a recent tag day and emergency fund drive.

Chicago Lying-In Hospital, $20,000, and trust funds for the maintenance of beds in the Chicago Lying-In Hospital, the proceeds of a performance of the Great Lakes revue.

Internal Medicine Congress.—At the annual meeting of the American Congress on Internal Medicine, held in New York City, December 31, the following officers were elected: president, Dr. Glentworth R. Butler, Brooklyn; vice presidents, Drs. Frederick Tice, Chicago, and Clement R. Jones, Pittsburgh; secretary-general, Dr. Frank Smithies, Chicago; associate secretary-general, Dr. Joseph H. Byrne, New York City, and treasurer, Dr. Augustus Caillé, New York City.

Influenza in the Large Cities.—In the forty-six largest cities of the United States the epidemic of influenza in the latter part of the year 1918, according to figures of the U. S. Census Bureau, made public, January 5, there were 111,688 death from this disease, which increased the combined death rate for those communities to 19.6 per thousand. Deaths from influenza were 69,439, with 42,149 deaths from pneumonia. The general influenza situation during the past week shows not much change from that of the previous week. In some communities a good many cases have appeared and restrictions have been continued, while in others the disease seems to be slowly subsiding and school and other restrictions are relaxed.

Welfare Work for 1919.—It is announced by the Rockefeller Foundation that the public health activities to be carried out during 1919 will consist chiefly of efforts against yellow fever, tuberculosis in France and malaria and hookworm disease in this and other countries, together with the completion of the war program already undertaken. The yellow fever commission is headed by Major-Gen. William C. Gorgas, who is now in South America in the interest of the work of the commission. The work on tuberculosis in France in cooperation with the American Red Cross will be continued at the request of the French government. The hookworm campaign will be continued in twelve states of this country and in twenty-one foreign states and countries. There are various other studies and investigations being carried on. An important feature of the work of the foundation is the development of training in modern scientific medicine in China, centers for which are almost ready for opening in Peking and Shanghai, in addition to the assistance given medical organizations already established throughout China. At the request of the War Department the War Demonstration Hospital will be continued, as will also the work of the Medical Division of the National Research Council, appointed by the President to coordinate the scientific resources of the nation, and the care and treatment of soldiers mentally and nervously disabled. The estimated income of the fund in 1919 is $6,750,000, of which about $2,250,000 will be for public health and somewhat over $3,500,000 for medical education.

FOREIGN

Fifth Interallies Food Supply Conference.—Four meetings of the scientific commission appointed for this purpose have been held, two at Paris, one at London and one at Rome, and the fifth has recently been under way at Rome.

Foreign Physicians in Spain.—The *Revista de Medicina y Cirugia Practicas* recently mentioned that since 1906 about sixty foreign physicians have been licensed to practice medicine in Spain. They are mostly German, English and North American physicians.

Bequest for Tuberculosis Hospital at Rome.—The rector of the University of Rome has accepted the bequest made by the late American princess di Vicovaro for the foundation of a modern hospital for the tuberculous, to be called the Eleonora (Lorillard) Spencer Cenci Hospital.

Organization of Insane Asylums and Colonies in the Netherlands.—The *Nederlandsch Tijdschrift* reports that all institutions that care for mental disease in the Netherlands—except the Roman Catholic—have recently organized, with headquarters at Utrecht, seeking to obtain better terms for supplies of various kinds. The medical department is not represented in the organization, as its aims are exclusively administrative.

Italian Institution for the Nervous Wrecks of the War.—Subscriptions have been collected and Senator Borletti has donated a handsome villa with extensive grounds near Milan for an institute to care for the *grandi invalidi nervosi* who need special and continuous attendance. The president of the association having the matter in charge is Prof. C. Golgi, who is also senator, with Prof. E. Medea as the medical chief of the new institution.

Medical and Welfare Activities in Italy.—According to the *Italian News Service*, committees have been formed in all the more important cities of Italy for the immediate relief and care of the children of soldiers and sailors crippled in the war. The children will be cared for, clothed and fed, and in the summer, according to the advice of physicians, will be sent to villas requisitioned or donated at the seashore or in the mountains.——A decree conferring power on the mayors of cities to fix maximum prices of medicines most in use has been issued. Heavy penalties have been provided for disregard of the regulations—fines up to $200, imprisonment for a year, and even requisition of the shops of pharmacists.

Pensions for Physicians Disabled in the Practice of Their Profession.—A bill was recently presented in the Spanish senate providing that disability contracted by any physician in the exercise of his profession should be considered as an occupational accident, and the widow and orphans of those who have died in consequence of inoculations and contagions professionally acquired should be entitled to an annual pension. The amount of the pension specified is 2,000 pesetas in towns of 200,000 inhabitants or over, and 1,000 pesetas in towns of less than 10,000 inhabitants, with intermediate amounts. The *Medicina Ibera* states that the bill was presented by Sr. O. Morejon and that the ministro de la Gobernacion is now considering it.

Prizes Awarded by the French Academy of Science.—Seven prizes for research in medical subjects were among those awarded at the recent annual meeting of this organization. One was given to Drs. Cardot and Laugier for their research on the electric stimulation of nerves; one to Dr. S. Chauvet for his monograph on pituitary infantilism; one to Prof. R. Dubois of Lyons for his works on physiology; another to Dr. H. Clement for his research on the action of centrifugation on living cells and living beings. One prize was divided between Nageotte and Sencert for their successful transplantation of dead tendons to repair gaps in tendons, and Drs. P. Duval and A. Grigaut for their research on traumatic shock. The Fanny Emden prize was not awarded but at the request of the donor the arrearages of the prize were given to the widow of Prof. A. Dastre, who was killed in Paris not long ago by a military automobile.

Demobilization of the Profession in Germany.—The *Paris Médical* relates that at the recent annual meeting at Eisenach of the delegates representing the organized profession, the Aerztetag, resolutions were adopted asking the authorities to demobilize first the older physicians, the married, and those who have been longest in the service. Also to appoint the medical officers in the army to points in or near their homes, and to reserve the posts of assistants in the universities for men returning from the front. Free graduate courses for those who desire them were also asked for, as well as special measures for disabled physicians. Another resolution asked that the instruments and automobiles released by the close of the war should be sold to physicians at moderate prices, without middlemen. It was also asked that no permission should be granted for foreign physicians to practice, especially at spas. The concluding resolution asked that circulars should be distributed explaining to the public how it is to their interest to return to their before-the-war physician.

Deaths in the Profession Abroad.—Prof. **B. Krönig**, director of the maternity and the clinic for women's diseases at the University of Freiburg, known best for his "twilight sleep" and intensive roentgen treatment of uterine cancer. ——Prof. **P. Jung** of the chair of gynecology and obstetrics of the University of Göttingen, aged 48.——Prof. **P. Kroemer** of the chair of obstetrics and gynecology at the University of Greifswald.——Dr. **H. Lohnstein** of Berlin, editor of the *Allg. med. Zentralzeitung* and of the *Zeitschrift für Urologie*, aged 53.——Dr. **A. Helweg**, a prominent psychiatrist of Copenhagen, aged 60.——Dr. **J. Eriksen**, a Danish ophthalmologist at Cairo where he served as consul for Denmark, aged 46.——Dr. **F. Sierra y Zafra**, physician in chief of the public hospital system at Madrid, aged 64.——Dr. **S. Pizjuan**, professor of surgery at the University of Sevilla, president of the Real Academia de Medicina and author of "De Re Clinica."——Dr. **J. V. C. Ingerslev**, a Danish physician who compiled the "History of Medicine in Denmark," and was the initiator of relief work in the profession in Denmark, aged 83.

Personal.—Prof. A. Sclavo of Siena has been called to the chair of hygiene at Florence as successor of Professor Roster who recently retired on reaching the age limit. Professor Sclavo has been a leader in matters of hygiene in Italy for years; has been active in organizing the training of sanitary officers in the army. He was also active in the organization of the prophylaxis of tuberculosis in the army.——The chair of anatomy at Rome, left vacant by the recent death of Prof. F. Todaro, is now filled by Prof. R. Versari of Palermo and Naples, known for his research on the anatomy of the bladder and on the embryonal circulation in the eye.——The University of Rome is said to have lost 235 of its students on the field of battle.——Prof. V. Bie of Copenhagen has recently been elected president of the Copenhagen Medical Society and consequently—according to the by-laws of the Danish Medical Association—this disqualifies him from serving as editor of the organ of the association, the *Ugeskrift for Læger*. He has therefore resigned the editorship which he shared with Dr. V. Scheel, and the latter assumes the entire responsibility for this important weekly.——Prof. F. Battistini of the chair of medical pathology at Turin, is recovering from a serious automobile accident.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Deaths in the Profession.—Dr. **V. M. Sotolongo y Lynch** of Havana, one of the founders of the *Abeja Medica*.——Dr. **J. B. Pons**, director of the first national sanatorium for the tuberculous in Cuba during its earlier years, and secretary of the Association of the Medical Press in Cuba.——Dr. **R. S. Gomez** of Buenos Aires, professor of internal pathology and descriptive anatomy at the University of Buenos Aires, and surgeon in chief of the Rivadavia hospital, aged 40.——Dr. **J. N. Acuña**, director of the schools of Buenos Aires, senator, at one time minister, and representative of Argentina in various international gatherings, aged 66.

Donation from Argentine Physicians for the War Fund of French Physicians and Their Widows and Orphans.—A committee was organized among the physicians of Argentina to collect subscriptions for the war fund for relief of physicians and the widows and orphans of physicians in France. The *Prensa Medica Argentina* gives a list of all who subscribed and the amounts, two giving 500 pesos each, one 300 pesos and about a dozen 200 pesos, others giving from 100 down to 5 pesos each. A total of 16,800 pesos was thus contributed, which was recently presented to the French minister at Buenos Aires, and a little cash added, bringing the total to 41,579 francs. The official name of the French Medical War Fund is the Caisse d'assistance médicale de guerre, and associated with it is the Secours de guerre à la famille médicale, both of which are under the patronage of the president of the republic.

CORRECTION

Incorrect Address.—In the article by Hall, Stone and Simpson, entitled "The Epidemic of Pneumonia Following Influenza at Camp Logan, Texas," published in The Journal for Dec. 14, 1918, page 1986, the address of Captain Simpson is incorrectly given as Hamburg, Ark. The correct address is Norristown, Pa.

MEXICO LETTER

Mexico City, Jan. 5, 1919.

Mortality from Influenza

According to statistics approximately estimated, the epidemic which has just passed over the country caused 436,000 deaths.

Death of Dr. Barajas

The recent death of Dr. Carlos Barajas is a distinct loss. He was a prominent physician, professor of anatomy in the Facultad de Medicina and also in the Escuela Nacional Preparatoria; was the author of various works of a general literary character and had started the publication of a manual of anatomy. He was also a popular lecturer and carried on an intelligent propaganda for the cause of the Allies. The government of the French Republic awarded him the "Palmas Academicas," and Sr. Viscomte Dejean, chargé d'affaires for France, presided at the funeral ceremonies.

The Association for Prophylaxis of Blindness

This new association has been doing good work, distributing circulars on the hygiene of the eye; has organized lectures by prominent ophthalmologists, and is planning a free dispensary for the care of eye affections. The association has collected by private subscription 11,000 pesos to defray its expenses.

Aid for the Red Cross

The postoffice authorities have placed on sale a special stamp that sells for more than the ordinary stamp, and the proceeds to be derived from this extra amount are to be handed over to the Mexican Red Cross. The public telephones installed in the postoffice, the use of which heretofore has been gratuitous, now bear a notice that a fee of at least five cents must be paid for each conversation over the telephone, and the sum thus realized will also be turned over to the Red Cross. The Red Cross has elected Sr. C. Hinojosa, director general of the postoffice service, an honorary official of the society in token of recognition of these services.

North American Medical Literature

The use of medical books published in English is beginning to be more common in Mexico. In three months the agent of a Philadelphia publishing house has obtained orders for more than $1,000 worth of medical books, and the interest is so great that certain physicians have joined classes in English in order to be able to read the works of the United States writers which are regarded here as excellent.

A Spanish View on German Science After the War

In a recent interview, the great histologist, Professor Cajal of Madrid, commented on the way in which military medicine and surgery has been dominating the medical literature of the world since the war began. Bacteriology is cultivated so that epidemics may be warded off. He remarked, "No one knows what has been going on in the Central Empires. Since 1915 they have been shut off absolutely from scientific communication with the rest of the world. It is probable, however, that the subjects related to the war predominate there also. I am convinced," he continued, "that when the war is over the rancor between the scientists of the opposing forces will continue. There will be much injustice and much silence. This will be the case much more than after the war of 1870; even then the scientists of France and Germany held aloof from each other for many years. But now the hatred of the savants of the Entente for those of German blood will be enormous, and will last a long time." He was asked whether they would be justified in this. To this he replied: "Unjustified from the scientific standpoint; justified as the punishment of Germany (justificada como escarmiento de Alemania). German science has lost its place in the front rank in this war. Now it is the United States which with incredible swiftness is marching toward the head of the line in science and in world progress." This interview forms the forty-eighth chapter in a biography of Cajal recently published at Madrid by A. del Olmet and J. Torres Bernal.

LONDON LETTER

London, Dec. 18, 1918.

The Last Struggles of the Army Medical Corps

In following the great British advance, which began, August 8, and continued for three months until the armistice was declared, the Medical Corps encountered great difficulties. Passing through the devastated country from Amiens to Le Cateau, the field ambulances and casualty clearing stations struggled to keep up with the fighting troops. As these pushed on faster and faster, the distances the wounded had to travel grew longer and longer. Moreover, although the attack was opened by one army, all the other armies were soon engaged, rendering impossible any interchange of surgical help. Although the casualty clearing stations traveled with less and less equipment, they never moved forward quickly enough, as adequate transport could not be obtained. As the advance became more rapid, the medical arrangements grew progressively simpler; the wounded had to be carried longer distances before operation, which seriously diminished their chances of benefit, even had the number of medical officers been sufficient to cope with all the cases. Moving ever forward and continually reducing their equipment, the accommodation of the casualty clearing stations was inadequate for the number of wounded coming from the field ambulances. Marquees often had to be pitched in a summary way, and when the weather grew colder the difficulty in getting fuel and enough blankets was great. Another trouble was that there were no disinfectors adapted for traveling on shell-wrecked roads. Owing to destruction of railway lines, the ambulance trains could not reach places where they were most wanted. When, November 11, hostilities ceased, the troubles of the medical service grew worse. The troops advanced without fighting, and the medical units had to push on behind them even faster than before; the clearing stations grew still lighter in equipment and weaker in medical officers. It was thought that because there were now no fresh wounded, the work would become much lighter. But in a few days there came toward the medical units a growing stream of released prisoners of all the allied nationalities abandoned by the Germans—underclad, unfed, many very ill, and all verminous. There also came an endless stream of influenza patients, many with severe attacks. Thus over bad roads, broken up by the ceaseless traffic of heavy motor lorries, the sick had to travel in motor ambulances through desolated country sometimes for five days before they could reach a railhead, and there the clearing stations were often so crowded that only the most severely ill could be retained. Here and there buildings could be found for clearing stations, but in many places the patients had to be housed in marquees hastily pitched on the mud.

Lead Poisoning of Children in Australia

It is curious that experience with lead poisoning in children is almost entirely derived from Australia, and that the literature on the subject is almost confined to Australian medical journals. The children are poisoned by handling painted fences, railings, etc. So serious is the danger that a deputation of the Queensland branch of the British Medical Association recently waited on the home secretary, asking him to include a clause in the bill to amend the health act dealing with the use of lead in paint on surfaces within the reach of children. Later a deputation of representatives of the Master Painters and Decorators Association waited on the home secretary to answer statements made by the British Medical Association. Finally a conference was held between the two bodies, and the following representations were made to the home secretary: 1. In order to prevent lead poisoning in children, it is necessary to prevent the powdering of lead paint within their reach. 2. As the powdering occurs on fences, palisadings and veranda railings exposed to the weather, it is necessary to use a paint for these surfaces that does not easily powder. 3. A paint should be used that is manufactured on a base of not greater than 60 per cent. of lead carbonate and not less than 40 per cent. of zinc oxid. Such paint should be ground by the manufacturer, either in paste or liquid form, and must bear the manufacturer's guarantee to the effect that it complies with this regulation. 4. The vehicle used in such paint should be a mixture of genuine pale boiled oil (linseed) and genuine raw linseed oil. 5. The surfaces specified above, and within the reach of children, must be painted every three years, in order to prevent powdering. It would be advisable that these surfaces be washed down annually. 6. The total prohibition of white lead is unnecessary.

The Treatment of Venereal Diseases

In a previous letter to The Journal, the precautions to be taken on demobilization to prevent the spread of venereal diseases to the civil populations were mentioned. The government has now opened negotiations with the naval and military authorities for the release from the army and navy of physicians experienced in the treatment of venereal diseases. It urges local authorities to arrange more frequent clinics at existing venereal disease centers by arrangement with the voluntary hospitals and otherwise, to hold evening clinics, if this is not at present done, and to provide many additional centers. The aim is to provide a center in every town with a population of more than 20,000. The appointment of whole-time venereal disease officers is urged. These officers should have considerable experience in modern methods and be under the supervision of the health officers. When necessary, part-time clinical assistants would be provided or a rota of physicians with special experience.

Drink Control

The shortage of food during the war led to great restriction in the production and consumption of alcoholic drinks. The effect on the amount of intoxication formed the basis of a paper by Lord D'Abernon, chairman of the Central Control Board (Liquor Traffic) on the causes of drunkenness. It might be supposed that excessive drinking is mainly due to bad environment, such as bad housing, insufficient amenities for food and refreshment, absence of healthy recreation, excessive number of saloons, and custom; or, on the other hand, that drinking is due to morbid predisposition of the individual. The importance of environment is shown by the statistics given in the accompanying tables, which contrast the positions before and after the drink traffic was controlled as a war measure. Thus, under a system of regulation of the conditions of drinking, reinforced by such indirect influences as the provision of canteen facilities, drunkenness in women, as compared with the year 1913, had been reduced by 60.6 per cent., their mortality from alcoholism and from cirrhosis of the liver had decreased by 69.1 per cent., and 51.5 per cent., respectively; the frequency of delirium tremens in women had fallen by 79 per cent., and the deaths from suffocation in infancy by 42.6 per cent. An even greater falling off had been brought about, within the same period, in the drunkards amenable to the inebriates acts. Thus, the number of persons proceeded against for habitual drunkenness in England and Wales in 1913 amounted to 332, but was only 27 in 1917. The admissions to inebriate reformatories similarly declined from 310 to 29—a result, however, to which other factors perhaps contributed.

EFFECT OF CONTROL OF DRINK TRAFFIC

Year	Convictions for Drunkenness	Deaths from Alcoholism, Excluding Cirrhosis of the Liver	Deaths from Cirrhosis of the Liver	Deaths from Suffocation in Infancy
1913	35,765	719	1,665	1,226
1914	37,311	680	1,773	1,233
1915	33,211	584	1,525	1,021
1916	21,245	333	1,163	744
1917	12,307	222	808	704

CASES OF DELIRIUM TREMENS TREATED IN CERTAIN POOR LAW INFIRMARIES (WOMEN ONLY)

	Number of Cases
Prewar, 1913-1914	214
Precontrol, 1914-1915	239
First year of control, 1915-1916	121
Second year of control, 1916-1917	45

PARIS LETTER

Paris, Dec. 5, 1918.

Heteroplastic Nerve Grafts

Dr. G. Roussy and Dr. A. Reverdin reported to the Société de neurologie their results from the use of heteroplastic nerve grafts according to the method of Dr. Nageotte, i. e., using pieces of nerves removed from dead-born calves, the grafts having previously been fixed in alcohol. Roussy and Reverdin treated the following cases in this manner: (1) A case of paralysis of the internal popliteal nerve, the result of complete division of the nerve, in the middle portion of the thigh, with separation of the ends for a distance of 5 cm. (the external popliteal being intact). After freshening the two ends of the nerve, a nerve graft, measuring 20 cm. in length, taken from the sciatic nerve of a dead-born calf, was interposed. (2) A case of complete division of the ulnar nerve in the axilla, with a separation of several centimeters and a cicatricial neuroma on each end of the nerve. A 10 cm. long nerve graft, taken from a dead-born calf, was interposed. (3) A case of division of the ulnar nerve, associated with causalgia of the median, the result of a wound in the middle third of the arm. A graft, 5 cm. long, from a dead-born calf was interposed. (4) A case of neuroma of the ulnar from a wound in the forearm which would not permit of the conduction of impulses through the nerve. The neuroma was resected, the ends of the nerve were freshened, and a 5 cm. graft from a dead-born calf was interposed.

These operations, the first of which was performed only nine months ago, are still too recent to permit of judging of the functional results which may follow from this procedure. However, it can be stated that the grafts are tolerated perfectly by the tissues. In no case has any local reaction manifested itself, and the wounds healed by first intention.

Medical Examinations

The minister of public instruction has addressed a communication to the rectors of the universities authorizing them to make a concession to medical students who have been called twice for the same examination at the end of the year in only one subject so that they do not need to take again the work of the entire year. These students will be permitted to continue their course of study without conditions until the March semester. But, in the event of another failure, the work done under this permission will be declared void and the whole year's work must be done over again.

Reorganization of the University of Strasbourg

The important question of the reorganization of collegiate teaching in Alsace and Lorraine is receiving the consideration of M. Lafferre, minister of public instruction. He has appointed a commission consisting of the deans of the faculties of science and arts, of savants and of professors, who will visit the scientific institutions, the faculties and the laboratories in these two provinces and report on the present condition and the needs of these institutions. A plan of reorganization of the University of Strasbourg will be submitted by this commission. The members of this commission are: MM. Paul Appell, dean of the faculty of science of Paris; Haller, director of the Ecole de physique et chimie and member of the Academy of Sciences; Haug, professor in the Sorbonne, member of the Academy of Sciences; Professor Roger, dean of the medical faculty of Paris; Guillet, professor in the Paris science faculty, etc. Nearly all the members of the commission were originally Alsatians. The mission will visit Strasbourg, Metz and Mulhouse, taking about ten days for the trip.

Admission to Hospitals of Progressive Cases of Tuberculosis

The under-secretary of state for the Service de Santé militaire has directed that all men with active tuberculosis, open or closed, can be admitted to the sanatorium hospitals, except the advanced hectic fever (mixed infection) and advanced cavity cases. Other tuberculous patients who should not be sent to these hospitals are (1) those suspected of having the disease and whose cases can be diagnosticated and disposed of in the centre de triage (evacuation hospital), or by consultation with the physician of the sector; (2) cases of pleuro-pulmonary sclerosis, the results of an old, long healed tuberculous process without any manifest or detectable symptoms, which can also be disposed of as the cases first mentioned.

Marriages

John Thomas Paine Wickliffe, Lieut., M. C., U. S. Army, Lebanon, Ky., to Miss Elizabeth Wolfe of South Carrollton, Ky., December 31.

Everett Morris, Capt., M. C., U. S. Army, to Miss Helen Bernedine Freer, both of Chicago, at New Haven, Conn., December 21.

Arthur Eugene Billings, Philadelphia, to Miss Mary Packard of Villanova, Pa., at Rosemont, Pa., December 23.

Charles Clifford Macklin, Pittsburgh, to Miss Madge DeGrofft Thurlow, at Philadelphia, September 17.

Frank Theophile Beatrous, New Orleans, to Miss Grace Phyllis Hayne of Boyce, La., December 26.

LaSalle Archambault, Albany, N. Y., to Miss Yvonne Archambault of Montreal, Que., December 26.

Raphael Schillinger, Brooklyn, to Miss Selma Lille of New York City, December 22.

Deaths

Henry Lincoln Dearing, Braintree, Mass.; Bellevue Hospital Medical College, 1890; aged 52; a member of the Massachusetts Medical Society; a member of the Association of Military Surgeons of the United States; a member and secretary of the local school board from 1882 to 1899; a member of the local board of health; lieutenant and assistant surgeon, Fifth Infantry, M. V. M., in 1901, and major and surgeon in 1905; died at his home, recently, from influenza.

Earle William Gilroy ⊕ Lieut., M. C., U. S. Army, Minneapolis; Rush Medical College, 1916; aged 25; who entered the service, Dec. 5, 1917, and at the time of his discharge, Dec. 8, 1918, was head of the department of pathology at the base hospital, Camp Wheeler, Macon, Ga.; died in Minneapolis, December 30, from pneumonia following influenza.

Melville C. Martin, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1882; aged 70; a Confederate veteran and commander of the North Georgia Brigade, U. C. V., for eighteen years chief surgeon of the Piedmont Air Line Railway, and for thirty years city physician; died at his home, December 19, from bronchial pneumonia.

Alpheus Alonzo Bondurant ⊕ Cairo, Ill.; Bellevue Hospital Medical College, 1875; aged 68; for many years recording and corresponding secretary of the Southeast Missouri Medical Association; died at his home, December 7, from the effects of a gunshot wound, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health.

Cornelius Williams, St. Paul; College of Physicians and Surgeons in the City of New York, 1874; aged 70; a member of the Minnesota State Medical Association, and once president of the Ramsey County Medical Society; a specialist in diseases of the eye, ear, nose and throat; died in St. Luke's Hospital, St. Paul, December 30.

Alfred James Weed, Granby, Conn.; College of Physicians and Surgeons in the City of New York, 1878; aged 61; who was struck by an automobile while crossing a street in Granby, December 24, sustaining injuries to his right leg; died in the Hartford (Conn.) Hospital, December 29, from bronchial pneumonia.

Moss McB. Bannerman, Shreveport, La.; University of Virginia, Charlottesville, 1885; aged 53; once president of the DeSoto Parish Medical Society; who was injured in a collision between a trolley car and his automobile, December 30, died at the Highland Sanitarium, Shreveport, December 31.

Mandaville W. McClain, Vera Cruz, Ind.; Curtis Physio-Medical Institute, Marion, Ind., 1895; American Eclectic Medical College, Cincinnati, 1896; aged 47; a member of the Indiana States Medical Association; died at the home of his sister-in-law in Bluffton, December 28, from heart disease.

Elmer D. Olmsted ⊕ Spokane, Wash.; Homeopathic Medical College of Missouri, St. Louis, 1878; aged 69; for three terms a member of the State Board of Medical Examiners; formerly mayor of Spokane; first president of the Chamber of Commerce of Spokane; died, about December 29.

Lewis U. Iverson, Christine, N. D.; University of Minnesota, Minneapolis, 1897; aged 54; died at his home, about December 26, from the effects of a gunshot wound of the head believed to have been self-inflicted, with suicidal intent, while suffering from a nervous breakdown.

Thomas Byram Vice, Flemingsburg, Ky.; Medical College of Ohio, Cincinnati, 1890; aged 51; a member of the Kentucky State Medical Association; president of the Fleming County Medical Society; died at his home, November 7, from bronchial pneumonia following influenza.

Carl Dinsmore Gray ⊕ Lieut., M. C., U. S. Army, Portland, Me.; Bowdoin Medical School, Brunswick and Portland, 1915; aged 32; who had received an honorable discharge from the Army, died while en route to his home in Portland, December 19, from complications following influenza.

Herman William Schlappi ⊕ Fulton, N. Y.; University of Buffalo, N. Y., 1904; aged 40; who was honorably discharged as lieutenant, M. C., U. S. Army, April 30; a Fellow of the New York Academy of Medicine; died at his home, November 21, from carcinoma of the stomach.

Sidney Charles Vermilyea ⊕ Lieut., M. C., U. S. Army, Poughkeepsie, N. Y.; University of Syracuse, N. Y., 1912; aged 31; assistant physician in the Hudson River State Hospital; who went overseas several months ago, is reported to have died in the service.

Clarence William Anderson, Rochester, Minn.; University of Louisville, Ky., 1911; aged 32; a member of the Minnesota State Medical Association; a member of the staff of the Mayo Clinic, Rochester; died in Red Wing, Minn., December 28, from heart disease.

Samuel Victor Rosenkranz ⊕ Lieut., M. C., U. S. Army, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1915; aged 28; died in the United States Marine Hospital, San Francisco, October 20, from pneumonia following influenza.

Frank Trimper Allen, Neodesha, Kan.; Northwestern University Medical School, Chicago, 1873; aged 69; a member of the Kansas Medical Society; division surgeon of the St. Louis and San Francisco Railroad; died at his home, January 2.

Thomas Joseph Courtney ⊕ Asst. Surg., Lieut. (j. g.), U. S. Navy, Worcester, Mass.; Tufts College Medical School, Boston, 1912; aged 32; who entered the Navy, Nov. 17, 1917, and was on duty at Norfolk, Va.; died at Norfolk, December 27.

William Sutherland Connery ⊕ Saginaw, Mich.; University of Michigan, Ann Arbor, 1889; aged 50; who served in the Navy during the war with Spain, and was for many years coroner of Saginaw County; died at his home, December 23.

Edward Merrick Semans ⊕ Delaware, Ohio; Miami Medical College, Cincinnati, 1890; aged 54; major and surgeon during the war with Spain; died at the home of his wife's mother in Portsmouth, Ohio, December 31, from heart disease.

Gerhard Frederick Hartwig ⊕ Lieut., M. C., U. S. Army, Young America, Minn.; University of Illinois, Chicago, 1915; aged 29; on duty with the Three Hundred and Fifty-First Infantry, A. E. F., in France; was killed in action, October 31.

John Darby Gaskins ⊕ Jacksonville, Fla.; College of Physicians and Surgeons in the City of New York, 1905; aged 38; obstetrician to Riverside Hospital, Jacksonville; died at his home, October 10, from double pneumonia following influenza.

Rufus Allen Thompson, Norwich, N. Y.; New York University, New York City, 1879; aged 65; once secretary and president of the Chanango County Medical Society; died in his office in Norwich, December 28, from heart disease.

Theodore LeGrande Burnett ⊕ Capt., M. C., U. S. Army, Louisville, Ky.; University of Louisville, 1913; aged 28; on duty at Camp Shelby, Hattiesburg, Miss.; died in that camp, November 5, from pneumonia following influenza.

Carl Ernst Hermann Graeb, Denver; College of Physicians and Surgeons in the City of New York, 1894; aged 55; formerly city chemist of Denver; whose license was revoked in 1907; died at his home, December 27, from dropsy.

Theron Nichols, South Pasadena, Calif.; Northwestern University Medical School, Chicago, 1867; aged 77; formerly of Milwaukee; a veteran of the Civil War; died at his home, December 29, from asphyxiation by illuminating gas.

William W. Hall, Toledo, Ohio; Northwestern Ohio College, Toledo, Ohio, 1885; aged 56; who was assaulted by a saloonkeeper, December 12; died in St. Vincent's Hospital, Toledo, December 19, from cerebral hemorrhage.

Royden Benedict Yoder ⊕ Lieut., M. C., U. S. Army, Northwood, Iowa; Hahnemann Medical College, Chicago, 1909; aged 33; died at Camp Custer, Battle Creek, Mich., December 9, from pneumonia following influenza.

John Herbert Bunn, Springfield, Ohio; Starling Medical College, Columbus, Ohio, 1902; aged 44; a member of the Ohio State Medical Association; died at his home, December 13, from pneumonia following influenza.

John Jennings Cleckley, Bamburg, S. C.; University of Maryland [illegible] a member of the South Carolina [illegible] at his home, October 24, from pne[illegible]

Edwin Emery Jones ⊕ Colebrook, N. H.; Dartmouth Medical School, Hanover, N. H., 1894; aged 48; was killed by the overturning of his automobile on an embankment near North Stratford, N. H., December 29.

Joseph Louis Swarts ⊕ Lieut., M. C., U. S. Army, St. Louis; St. Louis University, St. Louis, 1911; aged 33; a specialist in pediatrics; on duty at Fort Oglethorpe, Ga.; died at that post, December 24, from pneumonia.

George W. Smith, Minneapolis, Kan.; American Eclectic Medical College of Ohio, Cincinnati, 1879; aged 78; a veteran of the Civil War; died at his home, December 6.

Henry Kip ⊕ Paterson, N. J.; College of Physicians and Surgeons in the City of New York, 1877; aged 66; died at his home, December 23, from pneumonia.

Guthrie Olaf Burrell ⊕ **Lieut., M. C., U. S. Army,** Bucyrus, Ohio; Ohio State University, Columbus, 1916; aged 26; who went overseas in April, 1918; was killed in action, September 28, in France, death being due to a shrapnel wound of the head.

John Colavin McCabe, Hamilton, Ont.; Trinity Medical College, Toronto, Ont., 1886; aged 63; a member of the College of Physicians and Surgeons, Toronto; died at his home, November 18, from pneumonia.

John H. S. Reiley, Jr., Sardinia, Ind.; Medical College of Indiana, Indianapolis, 1904; aged 40; a member of the Indiana State Medical Society; died at his home, December 20, from pneumonia following influenza.

Willoughby K. Kistler, Leighton, Pa.; Bellevue Hospital Medical College, 1870; aged 72; a member of the Medical Society of the State of Pennsylvania; died at his home, December 27, from pneumonia.

George Anderson Cubbison, Erie, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; aged 55; a specialist in ophthalmology; died at his home, December 21, from pneumonia following influenza.

Edward Humphreys, Philadelphia, Hahnemann Medical College, Philadelphia, 1881; aged 61; a member of the Medical Society of the State of Pennsylvania; died at his home, December 25, from nephritis.

Lloyd Reuben Boutwell ⊕ **Lieut., M. C., U. S. Army,** Kansas City, Mo.; Washington University, St. Louis, 1916; aged 29; is reported to have died in France, November 14, from wounds received in action.

Eugene F. Taylor, Greensburg, Ky.; Kentucky School of Medicine, Louisville, 1892; aged 49; a member of the Kentucky State Medical Association; died at his home, October 26, from pneumonia.

Allen R. Ransom, Denver (license, Illinois, 1878; Colorado, 1892); aged 61; whose license was revoked in April, 1918; was found dead in his office in Denver, December 17, from heart disease.

Hugh Dyosephus Wood ⊕ Angola, Ind.; Bellevue Hospital Medical College, 1867; aged 83; a practitioner of Steuben County, Ind., for more than fifty years; died at his home, December 18.

William C. Fowler, Mount Sterling, Ill.; Missouri Medical College, St. Louis, 1887; aged 57; at one time a member of the Illinois State Medical Society; died at his home, December 18.

John Randolph Sloan ⊕ Stanley, Kan.; Kansas City (Mo.) Medical College, 1891; aged 67; died in St. Joseph's Hospital, Kansas City, Mo., December 6, from bronchopneumonia.

John William Beebout, Dexter City, Ohio; Starling Medical College, Columbus, Ohio, 1896; aged 47; a member of the Ohio State Medical Society; died, December 25, from nephritis.

James Marsh Jackson ⊕ Boston and Beverly Farms, Mass.; Harvard Medical School, 1891; aged 54; a member of the New England Pediatric Society; died at his home, December 27.

Elizabeth H. Trout, Chicago; Northwestern University Woman's Medical School, Chicago, 1884; aged 70; died at her home in Austin, Chicago, November 23, from pernicious anemia.

James Lawrence Schrote ⊕ Vanlue, Ohio; Eclectic Medical Institute, Cincinnati, 1886; aged 58; died at his home, October 22, from carcinoma of the liver.

George Rankin Hyde, Prairieville, Mich.; Bellevue Hospital Medical College, 1885; aged 65; elected probate judge in 1916; died at his home, December 14.

John E. Bahrenburg, Glendale, Calif.; Missouri Medical College, St. Louis, 1877; aged 61; died at the home of his son in Oil Center, Calif., December 23.

Oswald F. Rudolph, Corning, Calif.; Cincinnati College of Medicine and Surgery, 1885; aged 62; a member of the Medical Society of the State of California; died at his home, December 13, from heart disease.

John Stephen Herlihy, San Diego, Calif.; University of Buffalo, N. Y., 1909; aged 35; died at his home, December 21, after an operation for appendicitis.

John M. Wilkinson, Evart, Mich.; Philadelphia University of Medicine and Surgery, 1869; aged 73; died at his home, December 15, from influenza.

John Cooper, Blackfoot, Idaho; Eclectic Medical Institute, Cincinnati, 1870; aged 77; died at his home, December 16, from a nervous breakdown.

Isaac N. Myers ⊕ Maples, Ind.; Medical College of Fort Wayne, Ind., 1877; aged 64; died at his home, October 10, from cerebral hemorrhage.

Balthazar J. Meyer, Chicago; University of Christiania, Norway, 1877; aged 68; died at his home, December 30, from tuberculosis.

Jules LePanet Fremont, Quebec, Que.; Laval University, Quebec, 1909; aged 33; died at his home, October 12, from influenza.

George Edward Murray, Hagerstown, Md.; Hahnemann Medical College, Philadelphia, 1882; died, recently, at his home.

Darius G. Pickett, Fredonia, N. Y.; University of Buffalo, N. Y., 1874; aged 77; died at his home, December 27.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

"PLURIGLANDULAR" MIXTURES

Caps. Adreno-Spermin Comp., Caps. Antero-Pituitary Comp., Caps. Placento-Mammary Comp., Caps. Thyro-Ovarian Comp., Caps. Hepato-Splenic Comp., Caps. Pancreas Comp., and Caps. Thyroid Comp., Not Admitted to N. N. R.

After considering the evidence for the several "pluriglandular" mixtures described below, the Council declared them inadmissible to New and Nonofficial Remedies. The Council's action was communicated to the manufacturer, Henry R. Harrower, in accordance with the usual procedure. After giving due consideration to the manufacturer's reply the Council authorized publication of the report which appears below.

W. A. PUCKNER, Secretary.

With the offer "to supply you with as much literature as may be necessary and as little of the actual remedies as may be desired" if "the prospects for the inclusion of these formulas in N. N. R. are good," Henry R. Harrower sent the Council a booklet descriptive of his preparations and labels for the following mixtures:

Caps. Adreno-Spermin Comp., each said to contain "Adrenal Gland (total) gr. ¼, Thyroid Gland (U. S. P.) gr. 1/12, Spermin Extr. (from Gonads), Brain and Spinal Cord aa gr. 1, Calc. Glycerophosphate q. s. ad gr. 5."

Caps. Antero-Pituitary Comp., each said to contain "Anterior Pituitary Body gr. 2, Thymus Gland gr. 1, Thyroid Gland (U. S. P.) gr. 1/12, Calcium-phosphorus Comp. q. s. ad gr. 5."

Caps. Placento-Mammary Co., each said to contain "Desiccated Placenta gr. 2, Mammary Substance gr. 1½, Pituitary Body (total) gr. ⅓, Calcium-phosphorus Comp. q. s. ad gr. 5."

Caps. Thyro-Ovarian Comp., each said to contain "Desic. Corpora Lutea Ovarian Substance gr. 2½, Thyroid Gland (U. S. P.) gr. 1/12, Pituitary Gland (total) gr. ⅛, Calcium-phosphorus Comp. q. s. ad gr. 5."

Caps. Hepato-Splenic Comp., each said to contain "Liver Parenchyma, Spleen Substance aa gr. 2, Powd. Bile Salts gr. ½, Adreno-Spermin Co. (No. 1) gr. 1."

Caps. Pancreas Comp., each said to contain "Adrenal Gland, Pituitary Gland (total) aa gr. ½, Ovarian Substance gr. 1, Pancreas Substance q. s. ad gr. 5."

Caps. Thyroid Comp., each said to contain "Desic. Thyroid Gland (U. S. P.) gr. ⅛, Calcium-phosphorus Comp. q. s. ad gr. 5."

The Council declared these preparations inadmissible to New and Nonofficial Remedies, for reasons which follow:

1. Each of the mixtures contains one ingredient or more, which is neither recognized in the U. S. Pharmacopeia nor admitted to New and Nonofficial Remedies, namely: "Spermin Extract," "Brain," "Spinal Cord," "Desiccated Placenta," "Liver Parenchyma," "Spleen Substance," "Pancreas Substance" and "Calcium Phosphorus Comp. (Each 100 gm. represents Magnes. Phos. 1; Calc. glycerophos. 4; Potas. bicarb. 15; Sod. bicarb. 22 and Sod. chlor. q. s.)." For obvious reasons the Council does not accept a mixture containing an indefinite ingredient and hence it would be necessary as a preliminary for the consideration of any one of the mixtures that their unofficial ingredients be made eligible for New and Nonofficial Remedies by the submission of evidence that such ingredient is of uniform composition and that it is therapeutically valuable when given by mouth. There is no evidence that many of these organs have any value whatever when administered by the mouth or in any other way.

2. In the light of our knowledge the administration of gland mixtures in the host of conditions enumerated in the advertising circular is irrational and on a par with the use of the shotgun mixtures once in vogue.

Be it a pharmaceutical mixture, a "mixed" vaccine, or a "pluriglandular" product, the combination of two medicinal ingredients in a mixture must be considered contrary to rational therapy unless a good reason exists for such combination. Such mixtures are held in conflict with Rule 10 unless the manufacturer presents acceptable evidence for the value of his combination. A physician may prescribe any mixture which he considers indicated in a given case, but the marketing of mixtures of drugs in fixed proportions is in most instances irrational and a detriment to sound therapy.

Correspondence

"THE TREATMENT OF AMEBIC DYSENTERY WITH IPECAC BY RECTUM"

To the Editor:—In THE JOURNAL, Sept. 28, 1918, p. 1049, Dr. George B. Lawson gives the histories of two cases of amebic dysentery successfully treated by rectal injection of an unfiltered infusion of ipecac. He refers to Drs. Brem and Zeiler as being the first to administer the drug by the rectum and through the opened appendix. He also firmly believes in the amebicidic action of ipecac.

In an article in the *Grèce médicale* (**18**:6, 1916; abstr. J. A. M. A. **67**:474 [Aug. 5] 1916) I described how I was induced to administer ipecac by the rectal route years before the introduction of emetin hydrochlorid by Rogers, because of the intolerance of the stomach to ipecac administered according to the Brazilian method. I used a filtered infusion of lesser strength and volume than Lawson's by the rectal drip method, so as to have it absorbed. The symptoms of poisoning, often severe, proved that absorption was complete.

I did not aim at a local action of the drug on the ameba. As is known, that parasite in its vegetative phase does not lie free on the mucosa of the intestine, but is deeply embedded in its wall. Were this not true, then any other amebicide, especially silver nitrate, would effect a cure in amebic dysentery. No doubt emetin is a poison specially to amebas, as santonin is a poison for ascarides and as other agents are for other parasites. But even in the latter cases one must ask whether the action of the drug on the parasite is the result of contact, or does it follow after resecretion by the intestine of the previously absorbed germicidal substance? At all events, the action of emetin, injected subcutaneously, on amebas in the viscera, is not a direct one; the emetin reaches them diluted in the fluids of the body in a proportion of about 1:1,000,000; and it can be effected only by parasitotropy, which, by the rapidity of the circulation, brings the germicide in contact with the parasite in a short space of time.

This affinity shown by emetin for amebas is undoubtedly due to certain leukocytes. The action of pharmaceutic substances, when not immediately poisonous by coagulation of albumin or disintegration of cell structure, is a mediate one. They are subject to the general laws of nutrition—absorption and elimination. Their active course through the body is possible only by the intercession of the colloids, and the vast range of electric, organotropic energy is undoubtedly due to antigenic stimulation of cells. All function is based on fluctuations of the chemism of protoplasms and the physicism of solutions, and it is also by changes in their equilibrium that disease and recovery ensue.

As to the proper way for calling forth those changes, the shortest is not always the best. As we know, digitalis, specially directed to the organs of circulation, is less potent when directly introduced into the blood stream than when injected subcutaneously. Emetin seemed to me to belong to that class of substances, apparently offensive to the hematopoietic system and rejected by it in the fluids and tissues, being ultimately absorbed by degrees.

On the other hand, the various modes of administration of drugs are not equally adapted to the various remedial agents, even for the same drug in different form. I found that while the stomach is less tolerant to ipecac than to emetin, the reverse is true of the rectal route.

I. CECIKAS, M.D., Athens, Greece.

"THE TREATMENT OF HYSTERIA"

To the Editor:—There is so much that is good in Capt. J. M. Wolfsohn's contribution concerning the treatment of hysteria (The Journal, Dec. 21, 1918, p. 2057) that it is regrettable that he has added statements which negative a great deal of the positive part of his paper. His statement that "very little has ever been contributed to the treatment but volumes on the classification of hysterical disabilities" sounds peculiar when one remembers the volumes that have been written concerning hypnotism, reeducation and psychanalysis in the treatment of hysteria. He is modest enough at the beginning to say that the symptom is merely the outward sign, and that we wrongly say we have cured hysteria when we merely cure the hysterical symptom. Yet a little later he states that he cures more than 90 per cent. of the cases within the first twenty-four hours. The old methods of reeducation, combined with the use of mechanical adjuvants, he speaks of with kindly tolerance. He states that he cures in from one-half to one hour the same patients who had electrical treatment for six months by these old methods. Arousing our interest in this way, it comes as a disappointment when we later read that his methods consist also in the use of these mechanical measures coupled with peremptory commands. To quote from one of his cases: "He was finally treated with a mild faradic current and cured after three hours of treatment." To make matters worse, Captain Wolfsohn in his rules of treatment says that every case must be studied fully, and especially psychologically, before treatment is begun, and that this can even take the form of psychanalysis. How inconsistent this sounds in connection with his remarks in the earlier part of his paper that "he cures and completely cures more than 90 per cent. in twenty-four hours." If Captain Wolfsohn can make a complete psychologic study of every hysterical patient in one day, he is doing more than has heretofore been thought possible. However, I am sure he does not mean this but that he has allowed his enthusiasm to overrun his form of expression. Exaggeration and overvaluation of one's efforts is a hysterical trait, one of those often untouched and untreated manifestations of the hysterical psyche which the Captain speaks about in the earlier part of his paper. The importance of suggestion and the stronger influence that suggestion furnishes under military discipline perhaps explain the remarkable proportion of cure of symptoms he has effected. One gathers from his paper that he is a disciple of Babinski and a believer in the Déjerine isolation treatment but since "very little has ever been contributed to the treatment" he ignores those sources upon whose methods his own are based. In military circles one can do more than in civil life. "When the patient resists the cure," the Captain says, "this must be broken down by strong persuasion or by faradism." In civil practice, when the patient resists a cure the physician must desist because, as a rule, the patient goes to some other physician. This negatives also some short roads to a successful treatment which the Captain offers, such, for instance, as: "Do not discontinue the treatment until the cure is accomplished." And we feel that Rule 25, which says that "the secret of psychotherapy is a mental combat between the physician and the patient," is, to say the least, a rather unscientific and certainly unpsychologic point of view.

Edward E. Mayer, M.D., Pittsburgh.

To the Editor:—I have read the article on "The Treatment of Hysteria," by Capt. Julian M. Wolfsohn, with the hope of getting some new and really advanced ideas on the treatment of hysterical cases known on the firing line as shell shock cases. Many of these cases have been treated here in American base hospitals, with the exception that the injuries causing the condition were not received on the firing line; but these cases demonstrated all the points of interest that Captain Wolfsohn set forth in his interesting paper. In his final analysis, however, in laying down the cardinal principles of treatment, he fails, in my opinion, to state at least two, if not three, very important factors:

First, it would seem that at least many of these patients sustained some physical injury in combination with the hysteria, and that in all the cases he reports there was not one with a purely psychoneurotic disturbance alone. It has been demonstrated beyond a doubt that the patient who originally received a physical injury followed by some form of psychoneurotic symptoms is more easily cured: there is a physical fact from which one may convince the patient that he has recovered; and now that he is physically normal, he must be nervously normal as well.

Second, in the cases reported, all the patients were ill from a few weeks to many months. During that time, while waiting for the physical disturbance to clear up, the patient has been receiving subconscious mental treatment that has not been stimulated from the standpoint of intensive mental treatment by reeducation, which is a real fundamental principle in the treatment of all psychasthenic or psychoneurotic cases. In other words, the patient has undergone a real physical treatment with nervous and mental rest, and when the psychologic time arrives, he is cured almost instantly. This is beautifully illustrated by Wolfsohn's statement that some patients were cured in a few minutes, others in several or many hours, and others after days of anxious observation, waiting for that psychologic moment to arrive. The mental attitude of the patient has everything to do with this so-called spontaneous cure.

I simply make this criticism because the ordinary practitioner will not take into consideration the fact that hysteria without an actual physical cause is not as a rule cured in this way, and as easily as those cases in which some physical violence has been demonstrated or sustained. I could add a number of almost similar results, but it would be a repetition of what has been set forth in this interesting and valuable paper.

These two points, then, should be added to the twenty-seven general rules laid down: First, that the physical condition of the patient must be perfect ere treatment is begun for spontaneous cure, and second, that the long hospital treatment makes it possible to distinguish between a hysterical case with actual physical trauma and a case of purely nervous trauma.

Henry L. Stick, M.D., Camp Greene, N. C.
Captain, M. C., U. S. Army; Camp Psychiatrist.

ACTION OF DIGITALIS AND ATROPIN, WITH ESPECIAL REFERENCE TO THE HEART

To the Editor:—Digitalis affects the heart mainly in two ways: 1. It stimulates the pneumogastric center in the medulla, the resultant inhibition lessening the number of beats of the heart by prolonging the pause in diastole. Relaxation of fibers is increased; added rest is secured. Inhibition of some impulses from auricle to ventricle occurs—hence its value in auricular fibrillation. 2. It affects the heart muscle directly, increasing the strength of the ventricular contractions.

Atropin, in sufficient dose, paralyzes the inhibitory terminations of the pneumogastric in the heart, and stimulation of this nerve therefore causes no change in the pulse after its administration. Drugs have no effect in stimulating the pneumogastric after atropin has been given in sufficient dose to paralyze the inhibitory terminations. What is the sufficient dose? Cushny says 1 mg. (about 1/65 grain), and that the administration of sufficient atropin to paralyze the pneumogastric involves unpleasant dryness of the throat and difficulty in swallowing. The usual therapeutic dose of from 1/150 to 1/100 grain would apparently be insufficient to cause the paralysis. There is some uncertainty about this, however, as the susceptibility of individuals varies greatly.

If we grant, however, that the therapeutic dose of atropin has this effect in causing the paralysis of the inhibitory apparatus of the pneumogastric, are we justified in using it when we are using digitalis? Before answering this question we must consider what we expect or hope to accomplish with atropin. I am thinking of its indications in the extensive and progressive type of bronchopneumonia, lately so common. There is an impression among many clinicians that these patients are often relieved of cyanosis after using atropin. The cyanosis may be due to a moderate narrowing of the bronchioles already filled with mucous secretion, as asserted by a recent writer. According to Auer in the *American Journal of Physiology*, atropin prevents death in guinea-pigs subjected to anaphylactic shock by preventing the stenosis of the bronchioles. In beginning pulmonary edema it is commonly believed to be of value and is said to have an action on the permeability of the capillaries of the lungs, stopping the outward flow of fluid from the blood. These claims are made for it by several who have had large series of cases during the recent epidemic, including Keeton and Cushman, and Ridge. If, in the doses commonly given, it affects the inhibitory mechanism of the heart, we still have the effect of digitalis on the heart muscle, which effect is not influenced by atropin.

The two drugs are commonly used without paying much attention to these considerations; but there seems to be sufficient reason for keeping them in mind more than is customary. It is quite possible that small doses of atropin may be used in persons not especially susceptible to its effects, without seriously interfering with digitalis therapy; at least that is my conclusion from the foregoing.

William E. McCollom, M.D., Brooklyn.
Assistant Visiting Physician, St. Mary's Hospital.

"THE EFFECT OF 'GROUND GLASS' ON THE GASTRO-INTESTINAL TRACT OF DOGS"

To the Editor:—The article in The Journal, Dec. 28, 1918, p. 2127, on "The Effect of 'Ground Glass' on the Gastro-Intestinal Tract of Dogs," reminds me of a peculiar case in my practice: About thirty-five years ago a minister brought to me a diaper recently removed from an infant about 30 months old. A small quantity of fecal matter on the cloth showed a number of small pieces of broken glass mixed with it. The child had found the glass on the floor and, as usual, put it into its mouth, and finally swallowed it. There was no blood on the diaper, and, as far as could be determined, no untoward effects resulted.

G. W. H. Kemper, M.D., Muncie, Ind.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

INSTANCES OF LOW TEMPERATURE

To the Editor:—The temperature recorded in the following history seems to be about the lowest of which I can obtain any record. Will you tell me what is the lowest authentic temperature of which there is any record? A boy, 8 years old, with a severe pharyngeal diphtheria of eighteen days' duration, was admitted to the Rochester Municipal Hospital. He had received no antitoxin. The admission temperature was 99 F. In the next three days the temperature and pulse declined steadily, although not equally. Seven hours before death the rectal temperature was 91.8 F. Several thermometers were used and all agreed. Fifteen minutes before death the temperature rose to 94.4 F.

P. A. B., Rochester, N. Y.

Answer.—The lowest temperature on record, so far as we can discover, is that observed by J. J. Reincke (*Deutsch. Arch. f. klin. Med.* **16**:12, 1875) in a man who had spent part of the night outdoors, lying in a drunken stupor, exposed to a temperature of 32 F. At 8 a. m. the man's temperature by rectum was 75.2 F., and not until 1 o'clock in the afternoon of the following day did it return to normal. The man lived. Reincke also records the case of a man who jumped overboard from a transport, striking his head on a rock. He was picked up apparently dead, but vigorous attempts at artificial respiration proved successful. His rectal temperature was 91.7 F. Magnan (*Virchows Arch. f. path. Anat.* **53**:27, 1871) records the case of a drunken man whose rectal temperature was 79.8 F. Musser (General Diagnosis, 1900, p. 206) refers to a case of intermittent fever, with jaundice, in which the lowest recorded temperature was 91 F. He does not state whether the patient survived. It will be noted that these references are far from being recent. Perhaps some of the readers of The Journal may know of more recent references.

BENEDICT TEST—HILUM OF LUNG—KRÖNIG'S ISTHMUS

To the Editor:—1. In an article on diabetes which I read in The Journal, mention is made of the Benedict test. 2. and 3. In another article, reference is made to the lung hilum and to the isthmus of Krönig. As I have been unable to find in my books the meaning of these terms, I should appreciate your explaining them to me.

Luis Lazo Amiaga, M.D., San Salvador.

was properly excluded.

Liability for Injuries to Convulsive Patient—Evidence

(Connor v. O'Donnell (Mass.), 119 N. E. R. 446)

The Supreme Judicial Court of Massachusetts had here two cases: one brought by Mrs. Connor to recover damages from the defendant, a physician, for alleged negligence in his treatment and care of her after she had given birth to a child; the other, brought by her husband to recover consequential damages. The court, always referring to Mrs. Connor as the plaintiff, says that she filed specifications of the unskilfulness and negligence of the defendant, alleged in her declaration in substance as follows: The first specification alleged that the defendant negligently directed that the plaintiff, while suffering from convulsions following childbirth, be restrained and held in bed by holding her by her wrists, whereby her shoulders became dislocated and fractured; the second specification alleged that after the plaintiff's shoulders had been fractured and dislocated, the defendant failed to discover her injuries and negligently prescribed treatment which caused her great pain and resulted in permanent disabilities. The plaintiff testified that she went to bed at about 2 a. m., and was unconscious during the birth of her child; that she did not regain consciousness for a period of from twenty-four to forty-eight hours, and imme-

2. The hilum of the lung or hilum pulmonum is the depression on the mediastinal surface of the lung where the bronchus, blood vessels and nerves enter, and the reference in the article is to this region.

3. Krönig's isthmus refers to the apexes of the lungs behind and above the clavicles or in the area bounded by the clavicle and the borders of the trapezia, to the auscultation and percussion of which Krönig has called attention in the diagnosis of tuberculosis of the lungs.

DR. EDWARDS' *OLIVE* TABLETS

To the Editor:—Please advise me as to the composition of Dr. Edwards' Olive Tablets in the next copy of The Journal, but do not mention my name.

M.D., Chicago.

Answer.—These are purgative pills, and the claims under which they have been sold are either directly or inferentially misleading. The public has been given the impression that the pills owe their alleged virtue to the presence of olive oil. The American Medical Association's Chemical Laboratory made some cursory tests of the pills in 1913, and reported that they were essentially an aloes pill. These findings were substantiated by a more complete analysis made by the Connecticut Agricultural Experiment Station, which, in its report for 1914, declared that the pills contained dextrose, starch, aloes and ginger. A brief article on this product appears in the pamphlet, "Miscellaneous Nostrums," price 15 cents.

GERMICIDE IN THERMOMETER CASE

To the Editor:—There is a thermometer case that holds a small quantity of fluid to disinfect the thermometer while in the case. The use of alcohol in the case is *recommended* as the disinfecting fluid. Is alcohol an efficient disinfectant for this purpose? If not, what do you recommend?

C. R. Pickering, B.S., M.D., Muscoda, Wis.

Answer.—Various disinfectants have been recommended for use in the thermometer carrying case, the chief among them being formaldehyd and alcohol solutions. Formaldehyd is a slowly acting germicide and is irritant to some persons. Alcohol is probably as effective for the purpose as anything. When alcohol is employed, care should be taken that its strength be maintained between 50 and 80 per cent., otherwise its germicidal value is lessened; also the thermometer should be cleaned of all secretions before it is returned to the "aseptic" case. To be disinfected, the thermometer should remain *in* the alcohol solution at least thirty minutes, although a longer time is preferable. The case should be recharged frequently.

Society Proceedings

COMING MEETINGS

Southern Minnesota Medical Association, Mankato, Jan. 20-21.

SOUTHERN SURGICAL ASSOCIATION

Thirty-First Annual Session, held at Baltimore, Dec. 17-19, 1918

The President, DR. ISAAC S. STONE, Washington, D. C., in the Chair

Suture of Ruptured Kidney, with Report of a Case

DR. S. L. LEDBETTER, JR., Birmingham, Ala.: Early exploration is indicated in subparietal injury to the kidney, and suturing the ruptured kidney when possible is preferable to either nephrectomy or gauze packing. Nephrectomy should be reserved for those cases in which operation has been delayed and when the kidney is hopelessly damaged. Packing with gauze, when possible, is to be avoided on account of the delayed convalescence, the danger of secondary hemorrhage, and the possibility of infection.

Prostatectomy: Preparatory and Postoperative Treatment

DR. BRANSFORD LEWIS, St. Louis: I have adopted the suprapubic method as the operation of choice because it gives the better results. It is free from a number of momentous objections that pertain to the perineal operation, such as ineffectual urinary control, sexual disability, and urethrorectal fistula. While a one-stage suprapubic prostatectomy may be carried out with confidence and safety in a patient of middle age and good general condition, there is no doubt about the distinct advantages presented by the same operation done in two stages in the decrepit patient of advanced years and weakened resisting powers. The opportunity presented by the two-stage operation of establishing a firm adhesion between bladder and abdominal walls is scarcely less valuable than that of establishing suprapubic drainage. Infection of the loose connective tissues surrounding the bladder, with extensive suppuration, is one of the most serious dangers attendant on suprapubic work. Once established, such suppuration is difficult of control, and the condition may rapidly become formidable. The ounce of prevention consists in attaching the bladder firmly and permanently to the abdominal wall around the opening in the bladder by means of chromicized catgut sutures.

Spinal anesthesia is commended as serviceable by some operators, but I regard it as the most dangerous of all methods of anesthesia. I know of no deaths so far reported from the use of caudal anesthesia, although there have been instances in which physiologic effects have been observed.

DISCUSSION

DR. JOHN R. WATHEN, Louisville: The main thing in prostatic surgery is proper drainage and the avoidance of infection. I disagree with the statement that the in-dwelling catheter should remain in the urethra a considerable time. My experience has been that the in-dwelling catheter is not tolerated by the majority of patients for a considerable time, and some patients can hardly stand it at all. The suprapubic operation under local anesthesia is the operation of choice.

DR. ROBERT T. MORRIS, New York: After the suprapubic operation I like to fold the ragged fragments into place pretty well and pack them there with neat folds of iodoform gauze, leaving the end of the gauze protruding from the suprapubic wound; and for drainage I use little packs of sphagnum moss, allow the patient to turn on one side or the other, or abdomen, if he likes, and I depend on the capillarity of the gauze and sphagnum moss.

DR. FRANCIS REDER, St. Louis: A mortality following prostatectomy rests with the loss of blood. It is the constant bleeding in these cases that causes fatalities, and in the after-treatment of cases of prostatectomy I recommend the use of the Hagner bag for the control of hemorrhage.

DR. JAMES E. THOMPSON, Galveston, Texas: One of the most important tests as to how patients behave after operative procedures is the estimation of the blood urea.

DR. GEORGE A. HENDON, Louisville, Ky.: In suprapubic prostatectomy I pack the cavity from which the prostate has been removed lightly with iodoform gauze or plain gauze, allowing the ends to protrude from the suprapubic incision; but before doing so I put an ordinary Nélaton catheter into the bladder. The first twenty-four hours a lot of clots may form, but by irrigation with 6 or 12 ounces of warm boric acid solution, the lumen of the catheter is kept open and no clot is formed. All drainage takes place through the catheter in the urethra, and is collected by a urinal between the patient's leg. On the third day I remove the gauze packing, and all the drainage takes place below through the natural way. I have not had any suppuration or hemorrhages to make me dissatisfied with this method of treatment.

Irritable Bladder of Women

DR. CHARLES A. L. REED, Cincinnati: (This paper will be published in full in THE JOURNAL.)

Gauze Sponge Expelled Spontaneously from the Urinary Bladder

DR. G. PAUL LAROQUE, Richmond, Va.: Five years ago a woman was operated on and was told that the appendix and left ovary were removed and the uterus suspended. No drainage was employed. She remained perfectly well for five years and was then seized suddenly with agonizing bladder tenesmus, spasmodic incontinence of urine, and an enormous quantity of foul-smelling pus. Roentgen examination for stone was negative; there were no clinical evidences on examination. Cystostomy was not attempted on account of the violence of pain and the inability to hold water in the bladder. The body temperature varied from normal to 101 F.; the pulse varied from normal to 100. Vaginal examination detected a small mass in the right fornix.

There were no menstrual symptoms. On two occasions the patient had retention of urine, and the catheter withdrew on the first occasion a quart of foul-smelling pus containing urine, and a week later, when an attempt was made to catheterize her again, a piece of gauze was discovered in the urethra. This was pulled out and proved to be a surgical gauze sponge about 2 inches wide and 10 inches long. The symptoms immediately subsided. In a week's time she was well, cystostomy revealing a very small, almost completely healed fistula in the right side of the bladder. The mass could no longer be felt in the pelvis. In a week the patient left the hospital, and has remained perfectly well.

Malignant Papilloma of Gallbladder

DR. T. P. WARING, Savannah, Ga.: A woman, aged 42, had two attacks of puerperal insanity, one of them after an abortion. She had an attack of jaundice after the second attack of puerperal insanity. She has borne four children, three of them without trouble. The family history is negative as to cancer. The present trouble dates back three years, and starts with pain in the right hypochondrium and a feeling of relief on pressure. Three weeks before admission to the hospital, she felt a lump in the right side, followed a few days later by pain, which was not severe. There was no fever nor jaundice. The only symptom of cholecystitis was a constant feeling of indigestion. A distinct globular mass could be felt in the right hypochondrium, which was a little sensitive to pressure, but otherwise caused no discomfort. At operation a large gallbladder was found, rather dark in color and glistening; the walls were not very thick. Several masses could be felt in the gallbladder; and two small lumps along the cystic duct forming part of the tumor mass, apparently in the gallbladder itself, later proved to be enlarged lymph glands. The pathologist reported papilloma. The subsequent history bears out the malignancy of the papilloma, for although the dissection was clean and no other enlarged glands could be felt, the patient developed an obstructive jaundice three months later. This was relieved by establishing a hepaticoduodenal anastomosis over a rubber catheter, making use of the sinus wall to attach to the duodenum, covered and protected by the gastrohepatic and greater omentum. This gave absolute relief for four months. The patient declined further operation, and died two months later from the obstruction.

Congenital Diverticula of Intestine, with Tumor

DR. WILLIAM T. BLACK, Memphis, Tenn.: A fibromucous peritoneal polyp, weighing 4,260 gm., occurring in a woman, aged 59, was discovered during operation. This tumor sprang from the peritoneal coat of the tip end of an apparently congenital diverticulum in the lower sigmoid. A preoperative diagnosis was made of subserous uterine myoma, with cystic degeneration, or an ovarian tumor. The growth probably can be attributed to an embryologic condition or fetal "rest," or it might have followed a diverticulitis, ulceration or perforation of the diverticulum.

Resection of Cecum and Ascending Colon

DR. J. SHELTON HORSLEY, Richmond, Va.: I wish to call attention to the triangular space at the mesenteric border of the intestine which is sometimes infected by the operator before it is closed, and to the necessity of cleaning the bowel ends with antiseptics before suturing. A valve should be made when the small bowel is united to the large bowel. There is used a new operation based on these principles in which the end-to-end method is used and the ileum is projected into the end of the transverse colon and sutured in a manner similar to that used in my method of uniting the small bowel. In addition to this, in order to promote valve formation and increase safety, there is placed a row of interrupted mattress stitches of catgut. To relieve gas accumulation I suggest an enterostomy after the Coffey principle. I have done seven resections of the cecum and ascending colon in ten years. All these patients recovered from the operation satisfactorily. Two of the operations were for intussusception in infants, two for severe intestinal stasis, and three for hypertrophic tuberculosis. In one of the cases of tuberculosis a resection of several feet of diseased ileum was made after the cecum and ascending colon had been removed, thus making a double resection in this case.

Practical Considerations in Regard to Permanent Colostomies

DR. W. E. SISTRUNK, Rochester, Minn.: At present we are making a colostomy very similar to the one described by Mixter. This colostomy is, as a rule, made through a straight incision placed below and about 1 inch to the left of the umbilicus. It may be made through a low midline incision. The colostomy is made in a loop of the sigmoid flexure. After the loop has been lifted out of the abdominal cavity, an incision from 1½ to 2 inches long is made through its mesentery parallel to the direction of the blood vessels and extending upward nearly to the bowel. A second incision, about 1 inch long, is then made across the end of the first incision quite near the mesenteric attachment of the bowel. Two strips of gauze are placed in the upper end of the T incision which has been made, and when these are pulled apart a good sized opening is made through the mesentery. The two sides of the entire abdominal wall near the center of the incision are sutured through this opening in the mesentery. The remaining portions of the incision are then closed, a small bit of the bowel being included in two of the sutures to prevent the possibility of herniation of a loop of small intestine.

After removing the gauze, a glass rod or rubber tube is placed through the opening in the mesentery between the skin and bowel to serve later as a guide in cutting across the bowel. If necessary for gas distention, a small opening may be made in the bowel any time after twenty-four or forty-eight hours, and after five or six days the bowel is cut across completely with the cautery. As a rule, however, the patients pass gases very readily through the knuckle which has been brought up, and it is unnecessary to disturb it before five or six days. After the loop has been cut across it is found that the two ends of bowel are separated by the entire abdominal wall for a distance of from 1 to 2 inches. These ends protrude from 1 to 1½ inches above the skin. They may later be cut shorter if thought necessary.

Standardization of Rural Hospitals

DR. ISAAC S. STONE, Washington, D. C.: I am in favor of bringing the standard of all hospitals, whether large or small, up to that point which will afford the best service to the public and which will require the best medical and surgical training of the staff. Sufficient information has been collected to show the number of poorly equipped hospitals in all parts of the country, in towns and rural districts. Many of these hospitals are but little better than boarding houses without the essential equipment of house staff or laboratory, or, indeed, anything that justifies the name of hospital. It was suggested that all hospitals should be inspected by the health officer or commissioner of health, whether they are public or private institutions, and in case they are found up to the standard of requirement they should be duly licensed and required to send in a full report of the treatment of all cases during each year. I also favor state aid to rural hospitals when necessary, to provide hospital relief in country or remote outlying districts. Especial attention should be given to consideration of rural hospitals as social service centers and for the care of obstetric patients whose homes are remotely situated or who are unable to obtain competent professional attendance.

Treatment of Tumors of Upper Jaw with Cautery

DR. J. C. BLOODGOOD, Baltimore: Comparison of the results of operations for the removal of tumors of the upper jaw with the knife alone and results of the removal of identical tumors with the cautery discloses a decided decrease in the mortality. When we have accomplished cures it has been with less mutilation. Whether the actual number of cures has been increased cannot be stated at the present time. In many instances it is safer to remove the disease in stages.

It is remarkable how much can be done under local anesthesia alone. When a general anesthetic is necessary, chloroform, in my experience, seems to meet the indications best. It does not interfere with the use of the cautery. It is the best anesthetic when operations are performed in the region of the oral cavity. It should never be pushed to complete narcosis. The patient has no memory of pain, and although he is so lightly under the influence of the anesthetic that all reflexes are active, he remains more or less quiet. When chloroform is not pushed to complete narcosis, the danger seems practically eliminated, and the operations can be repeated at intervals of three or four days. In some of my cases there have been as many as fourteen operations. The pulse and blood pressure are recorded every five or ten minutes. The chloroform is rarely administered longer than one hour. When the cautery instead of the knife is employed, the operation can be discontinued at any moment.

The duration of the operation and the number of operations largely depend on the condition of the patient and the local extent of the neoplasm. When the cautery is employed it is possible to remove the tumor piecemeal and to destroy from the tumor tissue into the surrounding healthy tissue without danger of dissemination; while with the knife one must give the tumor tissue a wide margin and remove the entire mass *en bloc* at one operation. In the removal in stages with the cautery it is also possible to have microscopic control as an indication that enough has been done.

The new growth should be attacked with the cautery from two points: 1. One should burn the tissue at the border of the tumor. This not only destroys the infiltrating area, but excites in the healthy tissue beyond a granulation tissue which of itself is largely protective against secondary invasion, at least during the period of complete removal. 2. The second attack should be on the new growth itself, if possible, from the center out. These two methods of attack are varied according to the size of the neoplasm and its local growth, and the anatomic character of the surrounding uninvolved tissue.

Radium Therapy

DR. HOWARD A. KELLY, Baltimore: Some of the cases treated successfully with radium by me and my associates were: multinodular ovarian carcinoma; posterior mediastinal sarcoma, which had led to paraplegia; cervical Hodgkin's disease; universal Hodgkin's disease; medullary carcinoma of right breast and of glands of axilla and neck; extensive carcinoma of breasts; squamous cell cancer of larynx; extensive basal cell carcinoma of larynx causing obstruction; round cell sarcoma of tonsil and pharynx; unilateral tonsillar hypertrophy or round cell sarcoma; squamous cell epithelioma of mouth and of skin.

Treatment of Hodgkin's Disease

Dr. Curtis F. Burnam, Baltimore: During six years I have seen and treated more than 100 cases of Hodgkin's disease and malignant lymphoma. I advise against extensive operative removals. I employ radium treatment supported by rest in bed, forced feeding and iron. When radium is not available I urge the use of the roentgen ray. Better results are obtained when tissue examination is characteristic of lymphosarcoma than when it shows definite Hodgkin's disease. Also, in Hodgkin's disease the results are better when the polymorphonuclear leukocytosis characteristic of extensive Hodgkin's disease has not developed. Treatment is much more satisfactory in chronic than in acute cases. No routine treatment applicable to all cases can be prescribed. Each patient must be given individual attention. The best guide to treatment is to be found in the effects of the gland masses, the blood and the genral health of the patient. Gamma radiation at distances of from 1½ to 5 inches from the surface with amounts of radium varying from 500 mg. to several grams, the time of exposure being inversely proportional to the amount of radium employed, is indicated. The radiation should be carried out so that every affected part may receive adequate dosage, and the treatment should be repeated at intervals until all evidence of disease has disappeared.

The results obtained are highly encouraging. In cases in which lymphosarcoma was diagnosed, two patients have been well for more than five years, one with extensive neck, and one with abdominal, involvement; four have been apparently well for over three years, one with pharyngeal and neck involvement, one with mediastinal, one with tonsil, neck and groin, and one with neck and axillary involvement. One patient with mediastinal and neck involvement has been well for four years, and two patients for more than three years. One of these had neck, axilla, groin and iliac, and the other groin, axillary, neck and mediastinal involvement.

Reconstruction of Uterus

Dr. Charles R. Robins, Richmond, Va.: The blood supply of the uterus and the tubes entering from the sides makes it possible to remove as much of the intervening portion as may be necessary. The only thing necessary to leave is a continuous cavity from the tubes to the external os. This operation can most frequently be practiced in the treatment of fibroids. It is not intended that it should be generally used, because the cases in which it is indicated or possible are comparatively few. However, in young unmarried women and in married women who have not borne children, the operation would be justified often in whatever risk we might entail of unsatisfactory results or later development of fibroids.

Gynecologic Pelvic Drainage

Dr. J. Wesley Bovée, Washington, D. C.: There is still much need for the use of drainage material in pelvic surgery, preferably by the vaginal route. For this purpose I prefer to use paraffin-stearin gauze (Fisher). The chief advantages claimed for it are its nonadhesion to the tissues and consequent easy and painless removal, and its permiting endothelialization of denuded areas of pelvic peritoneum without the formation of lasting adhesions.

Visceroptosis

Dr. Charles L. Bonifield, Cincinnati: Some of my cases of ileosigmoidostomy have been under my observation for five years and are still doing well. In none have I found it necessary to remove the colon, although the colon was removed in one case by another surgeon while I was out of the city. I have always felt that his youthful enthusiasm led him to do an unnecessary operation. Some of the patients have had slight trouble with feces getting into the colon above the anastomosis, but in none of them has it been serious, and as time went on it became less and less frequent. I performed cecosigmoidoscopy on three patients, but my results were not as satisfactory as those obtained from ileosigmoidostomy. A large part of the fecal current continued to flow through the old channel and produced the old symptoms. The result of my study and experience with this condition would lead me to believe that many cases require no surgical treatment; that others require operative treatment only for the pelvic condition; others will require fixation of the kidney as well. For the type in which colonic stasis is most severe, ileosigmoidostomy is the best procedure yet devised; the colon should be removed at a second operation, and only when symptoms make it necessary.

Treatment of War Wounds in the Hospitals of the American Expeditionary Forces

Col. Charles H. Peck, M. C., U. S. Army: The scientific treatment of war wounds was developed greatly during the second and third years of the war in the French, British and Belgian services. It passed from the stage in which all wounds suppurated profusely, to the discovery of the Carrel-Dakin method of chemical sterilization, and later to the method of early "débridement," healing by first intention in a large percentage of cases. Successful early débridement depends on well equipped operating hospitals near the fighting line; on conditions of combat and transport which permit of evacuation of the wounded from the field to the operating hospital in less than fifteen hours, and on an adequate number of skilled operating teams to care for all wounded promptly in time of battle. These conditions have been met in the French and British services by the evacuation hospital and the casualty clearing station, established from eight to twelve miles behind the lines, and by large numbers of mobile operating teams which were moved as needed to meet the changing demands of battle at different points.

The American service was developed on similar lines, but soon had to meet the changed condition of open warfare as contrasted with the fixed line of trench fighting which had existed for more than two years. In open warfare the frequent delays in evacuating wounded from the field, the difficulty of providing for early operation near the front for all cases needing it, the necessity of using small mobile hospitals, and improvised operating units in field hospitals, instead of well organized evacuation hospitals, has interfered seriously with the ideal treatment of war wounds. In spite of these difficulties and new problems, the Medical Department of the American Expeditionary Forces has met the situation in a masterly way; has provided adequate hospitalization and skilled surgeons for the care of the wounded, and has performed this gigantic task for an army of 2,000,000 men with a minimum amount of confusion and delay. The excellent morale and physical condition of returning overseas wounded is evidence of the efficiency of the service.

Limitations of Cesarean Section

Dr. E. Gustav Zinke, Cincinnati: Abdominal cesarean section is positively indicated in all cases in which the child cannot be delivered by any means, dead or alive, through the parturient canal. The operation is not only justifiable, but almost imperative, and should be selected as the best mode of delivery in all cases of deformed, narrow and contracted pelves in which the diameters are so reduced in size as to forbid the test of labor, the use of the high forceps, or version of the child on the feet. Abdominal hysterectomy will furnish the best results for both mother and child in all cases of placenta praevia in which the hemorrhage is either profuse or moderate and protracted, and beyond control. When an elongated or unobliterated cervix or rigid os complicates placenta praevia, cesarean section is all the more imperative. Fortunately, in the majority of these cases, the hemorrhage may be arrested effectually; elongated cervices are quite rare; and an unobliterated cervix, or rigid os usually yields to well applied tamponade or the careful and skilful use of the rubber bag. Cesarean section may be chosen as a just procedure in cases of sudden and profound eclampsia, or severe toxemia in a primigravida when associated with an elongated or unobliterated cervix, acute suppression of the urine, general edema, and cyanosis. In the milder cases of this disease, when the life of the child is considered equally as important as, or more important than, the life of the mother, the operation finds a justification. This fact, more than anything else, renders cesarean section almost entirely unnecessary in the treatment of eclampsia. In cases of asthenia, both lives may be saved occasionally by performing this operation. In the past, cesarean section was not resorted to often enough; at present, it is performed too frequently. Cesarean operation should never be performed without the consent of an experienced consultant of recognized standing and an authority on obstetrics.

Judging from the favorable results reported by men who have performed cesarean section when the patients showed symptoms of infection, one is led to believe that the cases in which recovery did take place were not really of the type classified as true septic infection, but rather that they were cases of mild sapremia. A strictly septic infection is always systemic and almost invariably fatal; a sapremia is, usually, local in character, and the patient recovers notwithstanding the cesarean section.

10 Summary of 106 Cases of Mental Disorder of Unknown Etiology Arising in Fifth and Sixth Decades. E. T. Gibson.—p. 221.

6. **Central Canal of Spinal Cord.**—Of 206 spinal cords examined by Kramer the central canal was open throughout in fifteen instances, or 7.23 per cent. He has shown in previous studies how it is possible for a poison or an infective agent to reach the meningeal surface of the cord and the central gray matter and leave the rest of the cord unaffected; that it is possible for disease to spread through the medium of the cerebrospinal fluid upward, through the central canal and by diffusion therefrom into the central gray matter. Poliomyelitis is a disease of childhood. An ascending paralysis may also occur in adults though more rarely than in children. Kramer has also examined the cords from four cases of poliomyelitis in children and found the central canal patent in all of them.

Experiments were also performed in which it was sought to produce the condition found in acute poliomyelitis by injection into the spinal canal of dogs of small doses of dilute, 2 per cent. hydrocyanic acid (1 c.c.). On making this injection a motor paralysis of the posterior extremities, usually more marked on the left side, is produced. Such animals have been kept alive for a varying number of days, the motor paralysis persisting, sensation remaining unaffected. When the cords of these animals are examined, lesions typical of poliomyelitis are found. There is chromatolysis of the anterior horn cells, acute inflammatory exudate throughout the gray matter and in the perivascular lymph spaces, the central canal filled with a like exudate and a replacement fibrosis in the anterior horns.

7. **Content of Schizophrenic Characteristics.**—Summarizing in general review the content of the schizophrenic characteristics in cases showing dominantly an affective reaction, Greenacre emphasizes: (1) the prominence in depressions of the symptom constellation of ideas of reference with delusions of persecution and condemnatory hallucinations; (2) an analogous projection of the affect in the varied and dramatic hallucinations; the symbolistic attitudinizing, and the somewhat egotistical and constantly changing ideas of reference of the elation; (3) the determination of the content of the distortions of body sense and of the odd, fixed antic behavior by the underlying conflicts and personal difficulties.

9. **Pellagra at Connecticut Hospital for Insane.**—Five cases of pellagra are cited by Sandy. The first case, one of dementia praecox, paranoid form, after a hospital residence of over two years, presented the skin and mucous membrane signs of pellagra of a mild type, following persistent dietetic indiscretions. The physical signs of pellagra promptly disappeared when the patient was placed on a rational diet, there still remaining, however, a few quite characteristic sequels. The second case, also one of dementia praecox, but hebephrenic form, after a hospital residence of about two years, during a part of which time she had to be tube fed, developed the characteristic skin and mucous membrane appearances of pellagra. She was also tuberculous and finally died, the pellagra symptoms becoming more and more marked. The third case, one of dementia praecox, after some years of hospital residence in several institutions, developed pellagra symptoms. For several months prior to this she had persistently refused food and was tube fed. She failed to respond to treatment, death occurring about a month after the appearance of the characteristic symptoms.

The fourth case was one of dementia praecox. The patient had a positive blood Wassermann and had been given a series of mercurial injections. One month following the last injection the Wassermann had become negative, and about five months after admission, the peculiar skin eruption and mucous membrane changes made their appearance. This patient also developed an intractable diarrhea and died in about ten days after the eruption was first noticed. The fifth case was a rather high-grade feebleminded female with congenital absence of the palate and a positive blood Wassermann. Following a hospital residence of over five years, she developed the peculiar and symmetrical scaliness of the backs of the hands, associated with inflammation of the oral and genital mucous membranes and gastric disturbances. She had received mercurial injections, the last dose being given about two weeks before the development of the physical signs resembling pellagra. The skin and mucous membranes improved under treatment but the patient finally died a month later from cardiac degeneration. The patient appeared well nourished and there was considerable subcutaneous fat even at the time of death.

11. **Chemical Stimulation of Cerebral Cortex.**—Maxwell found that tetraethylammonium chlorid is *not only a stimulant* for medullated nerves, but that it is a more *powerful stimulant* of gray matter than creatin though less powerful than strychnin. Without any exception the contractions resulting from the action of the tetraethylammonium chlorid preceded by several minutes those caused by the creatin on the opposite side. In every instance a 1 per cent. solution of strychnin applied to the cortex on one side brought about the characteristic twitchings and convulsive contractions more promptly than the concentrated solution of tetraethylammonium chlorid applied to the other side. In a few experiments comparisons were made between tetraethylammonium chlorid and sodium citrate or sodium oxalate. In none of these was there any indication that the citrate or oxalate had a stimulating effect.

12. **Effect of Epinephrin on Blood Pressure.**—Intraspinal injections of 1 c.c. or 1.5 c.c. of epinephrin in the lumbar region of monkeys cause a rise of blood pressure distinctly different in character from the curve obtained after the intravenous injection of epinephrin. The curve of blood pressure following an intraspinal injection is generally characterized by a slow rise from the original level to the maximum height; by a plateau-like duration of the maximum; by a slow fall to the blood pressure which prevailed before the injection of epinephrin. An intralumbar injection causes a much more lasting effect on the rise of blood pressure than an intravenous injection. As a rule, after intraspinal injections the pressure at the end of the pressor effect has not been observed to fall below the original level. In human beings an intralumbar injection can be carried out with greater safety and certainty than in monkeys, hence the advisability of such studies in clinical physiology is quite evident.

14. **Blood Volume by Acacia Method.**—This method depends on an injection of a known amount of acacia into the blood stream and a determination of the dilution undergone by the acacia after time for mixing with the blood has been allowed. The acacia has been determined as furfurolphloroglucid by the method of Korber. The injection of 4 c.c. of 20 per cent. acacia per kilogram has been shown to be harmless to the animal; neither does it expand the blood volume during the time necessary for a determination.

16. **Blood Coagulation: Heparin and Pro-Antithrombin.**—The two new *fibrin* factors discovered by Howell and Holt are: First, a phosphatid, not previously described, which exists in *various* tissues but is found in greatest abundance in the liver. This phosphatid is designated as heparin to indicate its origin from liver. It inhibits coagulation, partially or completely according to the concentration. Second, a *substance* present in blood plasma and blood serum which is converted into antithrombin by a *reaction* with heparin. Just as in plasma and serum there is a mother substance from which thrombin is formed, so there is an antecedent substance from which antithrombin is *formed*. By analogy this substance is designated as pro-anti*thrombin*. Prothrombin is activated to thrombin by calcium, the pro-antithrombin is activated to antithrombin by heparin. Heparin may be obtained from lymph glands and it has been detected by its reactions in the uterine mucous *membrane*. It is present in largest amounts in the liver, especially the dog's liver. Heparin inhibits clotting mainly by preventing the activation of prothrombin to thrombin. It acts as an antiprothrombin rather than as an antithrombin. The action of heparin in preventing the activation of prothrombin and in causing the activation of pro-antithrombin is not destroyed at a temperature of 100 C. Pro-antithrombin in blood plasma is destroyed promptly by heating to 70 C. and more gradually by prolonged heating at lower temperatures, 60 C. Pro-antithrombin may *be precipitated uninjured from blood plasma by* acetic acid or by ammonium sulphate added to one-half saturation.

On the theoretical side, it is suggested that heparin and *pro-antithrombin* are normal constituents *of the* circulating blood (*not demonstrated for the heparin) and together fulfill* the function of safeguarding the *fluidity of the blood*, that is to say, of preventing intravascular clotting. The pro-antithrombin by its conversion to antithrombin provides a protection against any small quantities of thrombin that may arise in the circulating blood (metathrombin formation). The heparin in addition to functioning as a specific activator to pro-antithrombin exerts an inhibiting influence on the conversion of prothrombin to active thrombin. When blood is shed or when in other ways thromboplastic substance (cephalin) is added to the *blood the protection afforded by* the heparin is overcome and thrombin is *formed in amounts sufficient to cause clotting*. It is suggested by the authors *that variations in the amount of heparin in the* blood may suffice to explain *some of the known abnormalities in coagulation*, hemophilia, for example.

17. **Effect of Secretin Injections in the Rabbit.**—Fujimoto found in his experiments *that secretin, when injected subcutaneously, produces an increase* in the number of red and white corpuscles in the *circulating blood of rabbits, as Downs* and Eddy proved. The *hypodermic injection* of 1 c.c. of secretin causes an increase in the catalase content of the blood. Neither increase nor decrease in the diastase, glycolytic ferment and sugar of the blood was observed after the hypodermic injection of 1 c.c. of secretin.

23. **Blood Count During Digestion.**—During digestion there occurs an increase in the number of both the red and white corpuscles per unit volume of blood. Downs and Eddy found that these changes are comparable with the effects produced by the experimental administration of secretin. The source of the increased corpuscle content of the blood both in digestion and after the administration of secretin is an increased rate of production of new cells by the bone marrow. The similarity between the differential leukocyte counts in digestion and after the administration of secretin is additional evidence of secretin being the cause of the increase in the number of corpuscles during digestion.

24. **Periodic Variations of Knee-Jerk in Women.**—If the knee-jerk may be taken as a physiologic index of the tone of the nerve centers, the evidence obtained by *King points in* the direction of the conclusions, that there is a period of hyperexcitability immediately preceding, accompanying or following menstruation and that there is then a tendency toward a fall and an approach to an intermenstrual average.

42. **Aseptic Anastomosis of Intestine.**—Grey's paper is based on the results obtained from using the bulkhead suture (Halsted) in thirty-seven dogs. A new wire release ligature and a bolus of fibrin which is easily sterilized have been substituted for the paper cones. Specimens were secured following the operations at intervals varying from a few hours to 106 days. A study of the process of healing shows the following points: The process of repair in the bulkhead suture may, under favorable circumstances, lag but little behind that noted in the plain end-to-end anastomosis. On the average, however, the healing is a little slower in the former. A large inturn may not materially lengthen the period of regeneration, provided that the two inverted bowel ends remain about equal in size. The size of the inturn remaining after several weeks varies greatly from specimen to specimen. Frequently very little inverted bowel is found at this time. As a rule, there is a considerable delay in the repair of the mucosa when the two parts of the inturn are of unequal length, owing to poor approximation or to an inequaltiy in the necrosis on the two sides. This, however, does not appear to affect the function of the intestine. No striking difference was noted in the rate of repair between bulkhead sutures in which the cautery had been used and those in which the knife had been substituted for it. Stitches which puncture the epithelium usually delay the healing of the latter. Frequently such sutures carry a prolongation of the epithelium down into the deeper layers. Such adenoma-like prolongations may weaken the line of union where only one layer of stitches has been inserted.

44. **Relation of Supplying Ovary to Causation of Sex.**—The records of some 17,500 deliveries occurring in the Obstetrical Clinic of the Johns Hopkins Hospital from September, 1896, to March, 1918, were searched by Murray for suitable cases by which the principal theory advanced by Dawson could be tested. All those cases in which the location of the corpus luteum was actually demonstrated at cesarean section, at laparotomy for therapeutic abortion, at laparatomy within two weeks after delivery, or at postmortem examination, and in which there was no question as to the sex of the child, were tabulated. In all, seventy-five suitable observations were made on seventy women, five women each having two pregnancies. The corpus luteum was found to be in the right ovary in thirty-eight of the cases, and in the left ovary in thirty-seven of the cases. In 68 per cent., or in twenty-six, of the cases in which the corpus luteum was located in the right ovary the child was male, while in the remaining 32 per cent., or twelve cases, the child was female. On the other hand, in 57 per cent., or in twenty-one, of the cases in which the corpus luteum was located in the left ovary the child was male, while in the remaining 43 per cent., or in sixteen, of these cases the child was female. In this series there were forty-seven male and twenty-eight female children, 63 per cent., and 37 per cent., respectively. For the forty-seven males the corpus luteum was found in the right ovary in twenty-six, or 55 per cent., and in the left ovary in twenty-one, or 45 per cent.; while for the twenty-eight females the corpus luteum was found in the right ovary in twelve, or 43 per cent., and in the left ovary in sixteen, or 57 per cent.

From these figures Murray concludes that Dawson's theory cannot be correct, and, considering that the majority of the children in this series of cases are male, it is also clear that babies of either sex result in about equal numbers from the fertilization of an ovum from either ovary. Furthermore, clinical evidence shows that the determination of sex is probably not due to any factor present in the unfertilized ovum. The "chromosome theory" must be considered the only explanation of the causation of sex at present acceptable. The sex of an unborn child cannot be foretold, nor can either sex be produced at will, by any rules known at present.

64. **Specificity of Salicylates in Rheumatic Fever.**—A study of the comparative effects of nonsalicyl and salicyl medication made by Hanzlik and his associates does not show that salicylate possesses any unusual action or peculiar specificity in rheumatic fever. Prompt, though partial, relief was obtained in the majority of the patients receiving drugs other than salicyl. This is true for both early and late symptoms of the disease. In some of the patients the symptoms persisted despite salicyl medication, and in at least four cases (two of nonsalicyl-salicyl series and two of salicyl) the condition recurred shortly after salicyl treatment. In those patients in whom the symptoms persisted, although considerably moderated, after treatment with nonsalicyl antipyretics and analgesics, salicyl appeared to give more permanent relief. On the other hand, in two of the patients the fever persisted in spite of the salicyl medication. In some of the patients the persisting antipyretic effect during salicyl medication (although other symptoms of the disease were present) may be due to the retention or delayed action of the nonsalicyl antipyretic. With four of the nine patients unquestionably no effective and permanent relief from the symptoms of pain, fever, swelling of the joints, and general discomfort, was obtained until salicylate was administered.

Eliminating the elements of time, rest, and natural recovery, it appears that the relief of later symptoms is brought about more effectively and permanently by salicyl than by combinations of drugs whose pharmacologic actions are similar, but different chemically. The favorable reports of J. L. Miller with foreign protein and rest alone, and numerous recurrences of the disease in patients repeatedly treated with salicylate in large doses, lead the authors to the conclusion that salicylate possesses no thoroughly demonstrated specific action in rheumatic fever. It is no more than a symptomatic remedy which can be administered safely in very large doses, and represents a fortunate combination of both antipyretic and analgesic qualities which makes it much more suitable, and, also desirable for the treatment of rheumatic fever than combinations of opiates and various antipyretics. The injurious effects of salicylate on renal function and the kidney might be raised against the promiscuous and unwarranted use of the drug, but its efficiency and desirability as a symptomatic remedy in rheumatic fever may be regarded as outweighing the seriousness of these disturbances.

67. **Acute Suprarenal Insufficiency.**—The patient was 38 years of age, performing the more or less arduous duties of a military training camp. Early one morning he was found in a semiconscious condition in his room. A few hours later he was admitted to the hospital. By this time he was sinking into a state of coma. The picture was one suggestive of cerebral hemorrhage. The limbs were rigid, the reflexes gone, and the pupils distinctly dilated. The face and hands were cyanosed. The temperature was 99 F. Urine was normal. Cerebrospinal fluid showed no change and gave a negative Wassermann reaction. The patient died two and a half hours after admission. The clinical course was thus apoplectiform in type.

The necropsy was performed within two hours of death. The only organs exhibiting any marked pathologic change were the suprarenals. These were almost entirely destroyed, and converted into structureless, amorphous, yellowish masses, firm in texture, and considerably larger than the original glands. On the right side no trace of suprarenal tissue, either cortex or medulla, could be found. On the left a narrow strip of gland not more than 2 mm. in width was present at one point. This consisted entirely of cortex, the cells of which contained a lipoid substance which stained red with Scharlach R, but which was not anisotropic. The remainder of the gland consisted of areas of necrosis surrounded by the endothelial and giant cells characteristic of tuberculosis. No trace of medullary substance remained. Attached to the caseous mass was a small nodule which showed the microscopic structure of a sympathetic ganglion. The nerve cells and fibers of this ganglion, stained by various methods, showed no abnormality, but there appeared to be some increase of fibrous tissue.

70. **Application of Magnesium Sulphate to Scalds.**—Meltzer records results of experiments with external application in burns of a concentrated solution of magnesium sulphate carried out several years ago; the experiments were repeated since and similar results were obtained. The experiments were made on noninjured and nonshaved rabbits' ears. The animal was deeply anesthetized. About one third of each ear was submerged for a short period in hot water. Then the water was removed and one ear was submerged in a 25 per cent. solution of epsom salt (1 mol. $MgSO_4$+7 mol. of water) and the other ear was submerged in a solution of sodium chlorid (either 0.9 or 6 per cent.). The ears were kept submerged in these solutions for about two or three hours, the solutions being changed two or three times during this period. The experiments with submersion in water of temperatures between 56 and 63 C. have always shown that the inflammation of the ear which was submerged in $MgSO_4$ was undoubtedly retarded or nearly completely prevented.

Meltzer has also had occasion to see cases of burns in human beings. First and second degree burns were invariably arrested in their development when molecular solutions of $MgSO_4$ were applied early. Third degree burns, as a rule, ran a more favorable course under application of $MgSO_4$ than under any other treatment. Higher concentrations than 25 per cent. seem to exert a still better influence. The favorable action of the application of $MgSO_4$ in advanced stages of burns of second and third degree is less striking, especially on account of the infection present; but even in this stage it seems to exert a favorable influence and according to Meltzer ought to be used either in combination, or alternatingly, with antiseptics.

72. **Cause of Early Death from Arsphenamin.**—The earliest toxic symptoms noted by Jackson and Smith consisted in a dilatation of the heart, perhaps mainly of the right side at first, a progressively increasing pulmonary blood pressure, and a slow, gradual, but not severe, fall of the systemic pressure. The cause of this rise in pulmonary arterial tension they believe to be due partly to the alkalinity of the solutions of arsphenamin used, and partly to the specific action of the drug itself. With large toxic doses the right heart may have to contract against a pulmonary pressure increased by 100 per cent. above the normal, while at the same time the left ventricle may be contracting against a systemic pressure reduced by 25 to 50 per cent. below the normal. These peculiar conditions may tend to establish a state of increased irritability and instability in the heart, and in rare instances delirium cordis may result. The reactions of the internal organs when arsphenamin is injected are variable, and the reasons therefore are obscure. Apparently both central and peripheral influences are concerned. As a rule, oncometric tracings of the spleen and intestinal loop show a dilatation, while the kidney usually contracts, sometimes in a most vigorous fashion. The toxicity of arsphenamin is not increased by the breathing of high concentrations of carbon dioxid, nor by the injection of calcium hydrate, calcium lactate, or of monosodium phosphate. A number of intermediary compounds occurring during the process of manufacture of arsphenamin were studied by Jackson and Smith. None of these is very poisonous and they cannot account for the variable toxicity of different samples of arsphenamin which may or may not contain traces of one or more of these. The suggestion is made that in those cases in which severe, acute, toxic symptoms suddenly manifest themselves, either during or shortly after the intravenous injection of arsphenamin, tyramine is more likely to be of benefit to the patient than is any other known drug.

73. **Increasing and Decreasing Oxidation.**—Evidence is presented by Burge to show that depressants such as the narcotics decrease oxidation which may be the cause of the depression by producing a decrease in catalase, while stimulants such as caffein and theobromin produce an increase in oxidation which may be the cause of the stimulation by producing an increase in catalase. The fact that the action of caffein and theobromin is to produce an increase in catalase with resulting increase in oxidation while the action of the narcotics is to produce a decrease in catalase with resulting decrease in oxidation is offered as an explanation for the antagonistic action of these substances.

84. **Plastic Repair of Urethral Defects.**—Legueu reports three cases, the only ones, he says, of which he has knowledge, in which this procedure was employed. One patient showed as a result of several attacks of gonorrhea, multiple urethral strictures. As the results of instrumentation infection occurred, a perineal fistula developed and the penile urethra became totally occluded from perineal fistula to meatus, the meatus itself being completely obliterated. This part of the urethra was palpable as a fibrous cord as thick as a goose quill. The penile urethra was reconstructed by a tubular graft of vaginal mucous membrane. In the course of a colpoperineorrhaphy, a rectangular segment of vaginal mucosa was excised. This was dropped for a few moments in warm artificial serum, then rolled about a 26 F. bougie its edges caught with fine catgut so as to form a tube about 8 or 9 cm. long. The bougie carrying the graft was then introduced into a tunnel previously made in the glans penis when the sclerotic urethra was excised, and placed in the gutter left by the excision of the anterior urethra, care being taken to place the line of grafted suture in the angle of the two corpora cavernosa. The end of the bougie was introduced into the urethra and this sutured end to end to the graft by an interrupted catgut suture. The superficial tissues were united in two layers over the graft and a small drain left in place, the outer extremity of the graft being sutured to the meatus. The bougie was withdrawn on the morning of the third day. The operative result is excellent. In the other two cases equally good results were obtained.

Certain general preliminary conditions are essential to the success of the operation. They are the following: 1. The resection must be preceded by a temporary urethrostomy which involves the suture to the skin of both ends of the wounded urethra. After making this urethrostomy, several months must elapse before applying the graft in order to work on uninfected tissues. The orifices must also be dilated in order to prevent stricture. 2. Suprapubic cystostomy. It is preferable to establish this before the urethrostomy. Perineal diversion of the urine is not satisfactory since it leaves a more or less infected wound near the point of grafting. The tissue should be prepared by tunneling.

85. **Unique Urethral Obstruction.**—Striking the perineum on the corner of a box caused a tear of the bulb with the formation of a sac which occupied almost the entire perineum. The sac was lined with glistening mucous membrane throughout and extended up around the urethra into the region of the scrotum on either side. Portions of the bulb were found on either side of the sac. A new urethra was formed from the wall of the sac.

86. **Ureter Obstruction by Tuberculosis Mesenteric Lymph Nodes.**—In the three cases reported by Hepburn the gland was compressing the ureter. The diagnosis was made with the aid of the roentgen ray. Removal of the glands by operation gave relief in each case.

87. **Experimental Pyelitis in Rabbit.**—Pyelitis was experimentally produced by Helmholz and Beeler in the rabbit by the intravenous injection and by the intravesical injection of *Bacillus coli-communior* isolated from spontaneous pyelitis in the rabbit. Pyelitis was produced in seventeen of thirty-one rabbits injected into the ear vein. Ten per cent. of the rabbits had also abscesses in the kidney. Three rabbits had abscesses without a pyelitis. Pyelitis was produced in ten out of fifteen rabbits by intravesical injection. In only one instance were there abscesses in the kidney.

125. **Multiple Osteoma of Nasal Accessory Sinuses.**—Culbert cites a case of multiple eburnated osteoma involving the frontals, ethmoid, right orbit, middle and superior turbinates and cristi galli, and protruding into the cranial cavity. As this osteoma was so large and involved so many sinuses it was impossible to remove it as a whole, so that no exact size, shape, measurements, nor weight could be obtained; consequently, the size must be determined as far as possible by measurements of the shadows in the roentgenograms. In the frontal sinuses and the right orbit, this osteoma was one solid, continuous growth; but in the ethmoid region, it was composed of several nuggets, some of whose faces articulated perfectly. They resembled the tight overlapping of peanuts in a shell. In the operation, the result of this articulation was that when a part of one face was bitten off, the combination was unlocked with liberation of the remainder of that portion. These peculiarities of growth seem proof to the author that this multiple osteoma had several foci, which were, possibly, the frontal sinus, the junction of the frontal and ethmoid, the ethmoid, and the turbinates, and that all these different simultaneous growths were finally jammed and molded together. This growth covered a period of at least ten years. Although at necropsy an abscess was found in each frontal lobe, no sign or symptom referable to them had presented during the patient's life, with the possible exception of the last few days.

141. **Protein Sensitiveness.**—The reactions of twelve asthma patients were tested by Sterling to the following food proteins: Egg yolk, egg white, milk, casein, cheese, herring, beef, chicken, lamb, pork, wheat, rice, potato, barley, cocoa, radish, beet, cabbage, onion; also horse serum, and cat's hair, dog's hair, horse hair. Only one of these patients exhibited a positive reaction, a woman who showed erythema and a slight wheal, to pork, to cabbage, to rice and to radish. The patient's own statement corroborated the test thus far, that these foods always aggravated or brought on an asthmatic attack; but although she had excluded them from her diet for the last ten years, she is still subject to recurrences of asthma. The other asthmatics tested could not give a definite statement as to the effects of any particular food on their paroxysms. Six patients were benefited by subcutaneous injections of gradually increasing doses of foreign vegetable proteins.

142. ***Value of Autogenous Vaccines.***—Womer used autogenous vaccines in 100 cases of arthritis, acne, abscesses, boils, carbuncles, endocarditis, eye and ear infections, infections of the hand, nasal sinuses, pyorrhea, respiratory conditions and urinary infections. Of these 100 cases 87 per cent. of the patients recovered completely, 13 per cent. did not. The most satisfactory results were obtained in infections of the skin and subcutaneous tissues. The results in respiratory conditions were not encouraging. All of the ear cases recovered except one, and this case was subsequently found by roentgen ray to have a very extensive involvement of the mastoid region. The improvement in many cases was very slow and the treatment was persisted in for many months.

5 Hysterical Tremor. W. Johnson.—p. 627.
6 *Complement Deviation in Cases of Malaria. J. G. Thomson.—p. 628.

1. **Bent Back of Soldiers.**—Considerable experience with this condition has convinced Hurst that the bent back of soldiers, however variable its etiology, is constant in its pathology, being always hysterical in nature, and consequently always curable by psychotherapy. The most common cause is a blow in the back, either due to the explosion of a shell hurling a man against the side of a trench or causing the parapet to fall on him, or to some accident which might equally well have occurred in civil life, such as being jammed against a wall by a lorry. Occasionally an actual wound is present, but this is always superficial, the spine itself having escaped.

The one common factor in these various causes is pain, generally in the back, but occasionally in the abdomen, which is relieved by bending far forward. After a time the pain caused by the blow on the back, rheumatism or other exciting cause, diminishes or disappears. The patient can now often rest comfortably lying flat on his back, but he continues to stand or walk in the same bent position. The pain has gone, but the posture, adopted with the object of relieving it, remains. Numerous investigations with the roentgen rays have shown that there is no organic spinal lesion, even in those cases which follow a severe blow on the back. The appearance of the patient is so characteristic that the diagnosis is at once obvious, as there is no organic condition which in any way resembles it, except *spondylitis deformans*, which, however, never affects young men Moreover, the position assumed in the latter is the same whether the patient lies down or stands, whereas the bent back of soldiers almost invariably disappears entirely, or almost entirely, on lying down. All forms of treatment except psychotherapy are useless.

3. **Cause of Rickets.**—The authors' experiments on dogs seemed to show that some other factor than diet is the prime cause of rickets in dogs, and they afford no evidence that milk fat (butter) contains any accessory factor protecting against the development of rickets. Pups kept in the country and freely exercised in the open air, although they had actually a smaller amount of milk fat than those kept in the laboratory, remained free of rickets, while the animals kept in the laboratory all became rickety.

6. **Complement Deviation in Cases of Malaria.**—A specific antigen for malaria has been prepared by Thomson from a culture of malaria parasites secured from as heavily infected a case as possible, according to the method described by J. G. and D. Thomson. The best antigen obtained by Thomson acted well diluted 1:30 with normal saline. The antigen must be titrated before use to estimate the minimum dose of complement required to use in the test. The patient's serum is diluted 1:10 with normal saline. Put up for each serum four tubes, three of which contain antigen, the fourth being the serum control. Into the three tubes containing antigen introduce two and a half, three, and three and a half doses of complement, and two and a half doses are added to the serum control. An antigen control is put up with each series. The method used is long fixation in the cold, the tests being kept over night in the ice chest. In the morning the sensitized red cells are introduced, and the results read after fifteen minutes in the water bath at 37 C. Thomson has performed tests on the serums of 200 known cases of benign and malignant tertian malaria, with or without parasites in the peripheral blood, and at all stages of treatment by quinin. After short courses of treatment the blood serum gives positive results, and in many cases he has obtained positive results, after a considerable amount of treatment; but the reaction tends usually to become weaker. After very prolonged treatment and in cases where there has been no attack of malaria for many months the blood serum usually gives a negative result. It is interesting to note that the serums of syphilitic patients give a positive result with this antigen, and it is necessary to exclude this disease.

16. **Leprosy Treated by Gynocardates.**—Nine cases of the maculo-anesthetic form of leprosy and four cases of mixed leprosy were treated with sodium gynocardate A by Carthew. All lesions disappeared in two cases; very marked improvement occurred in three cases; considerable improvement occurred in six cases; improvement in one case and no improvement was noted in one case. Neither the duration nor the type of the disease seems to have any marked influence on the rapidity of the improvement. In Carthew's opinion, the relief granted to the patient by the improvement of his general health, together with the almost universal improvement of the symptoms of the disease, indicate that the treatment by sodium gynocardate A is indicated in all cases of leprosy of whatever type or duration.

28 *Treatment of Extensive Septic Wounds. H. Gardiner.—p. 777

23. **Influence of Diet on Teeth Formation.**—The investigation made by Mellanby was undertaken primarily with the object of studying (1) the factors involved in the development of sound teeth and of the growth of the jaws in relation to the size of the teeth, and the factors bearing on the immunity of erupted teeth to caries and other diseases. The author discovered that hypoplasia of the teeth is caused largely by a deficient diet and that the factor in the diet which controls the calcification of the teeth is something of the nature of an accessory food factor (vitamin). This factor has a similar distribution to that of fat-soluble A, which is largely responsible for the calcification of bone, a deficiency of this substance in the diet being followed by the development of rickets. Puppies were used in this investigation. A diet containing in abundance those articles with which the fat-soluble A accessory food factor is associated, such as cod liver oil, butter, etc., allows the development in puppies of sound teeth. A diet otherwise adequate but deficient in the substances with which fat-soluble A is associated brings about the following defects in puppies' teeth: (a) delayed loss of deciduous teeth; (b) delayed eruption of the permanent dentition; in some cases the delay in the eruption of the permanent teeth is more marked than the delay in the loss of the deciduous teeth; (c) irregularity in position and overlapping especially of the incisors; (d) partial absence of or very defective enamel; (e) low calcium content; the deficiency in calcium salts may result in the teeth being so soft that they can be cut with a scalpel. The evidence makes it clear that this is an instance of diet affecting the teeth from the inside and is independent of bacterial sepsis and other oral conditions associated with food.

25. **Antiscorbutic Value of Root Vegetables.**—The results of the experimental work reported on here by Chick and Rhodes are strongly in support of those medical authorities who recommend the inclusion of some extra antiscorbutic in the diet of infants nourished on milk of which the original antiscorbutic value has been diminished by heating or drying. The experiments were made with young guinea-pigs. The juices were prepared by rubbing the clean-cut surface of the raw vegetable on an ordinary kitchen grater, placing the pulp in muslin and squeezing gently between the fingers. The juice was always prepared fresh every day. Expressed raw vegetable juices undergo changes rapidly at room temperature, and were found to deteriorate in respect of antiscorbutic value when stored even at a low temperature in a refrigerator. The raw juices of swede (turnip), carrot, and beetroot were used. The juice of the fresh raw swede (turnip) easily takes the first place in respect of antiscorbutic value. Protection from scurvy was attained with a daily ration of 2.5 c.c. In case of raw carrot juice, severe scurvy developed in animals receiving daily rations of 5 c.c. and 10 c.c.; with a daily ration of 20 c.c., protection from scurvy was secured and the general condition of the animals was about the same as of those receiving a daily ration of 2.5 c.c. swede (turnip) juice. In case of beet root, the antiscorbutic value was less than that of carrot; animals receiving a daily ration of 20 c.c. fresh raw juice showed only a small degree of protection, acute symptoms of scurvy supervened in every case, and several deaths from scurvy occurred before the period of experiment, three months, had expired.

28. **Treatment of Extensive Septic Wounds.**—Gardiner has been treating septic wounds with much discharge with no permanently applied dressing. The ordinary incisions for opening up recesses in pockets are made as soon as the patient has recovered from the result of transfer to the hos-

pital. Incisions and openings so made are performed with the idea of obtaining the maximum effect of gravity in the subsequent treatment. The wound is then packed with gauze and bandaged in the usual way, the sole object in this being to assist in stopping oozing of blood. All dressings are removed forty-eight hours later. The wound is then syringed with some mild antiseptic, for example, boric or weak eusol lotion. A guard made from perforated zinc, cut in an appropriate size and bent in the form of a cradle, is placed over the limb or part wounded and covered by a sterilized towel. If possible, an ordinary cradle is placed over the whole. Any discharge from the wound is allowed to run out from the wound, and is taken up by a sterile pad of wool of sphagnum moss so placed as not to touch the wound. At intervals varying with the amount of discharge, on an average twice a day, or in some cases more frequently, the nurse lifts the towel and zinc guard, syringes or swabs the wound, and changes the pad. The guard and towel are then replaced. This treatment is continued until all pockets and recesses have been closed by granulation, the granulating surface is smooth, and the discharge has practically ceased. The wound is then dressed in the ordinary way with gauze and wool. Forty or fifty cases have been treated in this way, and in none of them have any bad effects been observed as the result of leaving the wounds open. In some of these the wounds were so extensive, and the discharge so foul and profuse, that amputation on admission was seriously considered. Wounds infected with a great variety of organisms —all those commonly met with in such wounds—have been treated in this way with success.

36. **Treatment of Sepsis by Ionization.**—Treatment of sepsis by zinc ionization consists in the introduction of zinc into the septic area by means of the electric current. The solution of zinc sulphate ordinarily used contains: zinc sulphate, 0.25 gm.; alcohol, 0.75 c.c.; water, to 100 c.c. But when it is desired to have the solution viscid, so that, for example, it may adhere to a sloping surface, gelatin is an ingredient: zinc sulphate, 2 gm.; gelatin, 15 gm.; water, to 100 c.c. Friel has found that ionization with zinc is successful in middle-ear suppuration, empyema of the maxillary, of the frontal, and of the sphenoidal sinuses; impetigo of the face, eczema, ulcers of the arms or legs; some wounds.

41. **Treatment of Malaria.**—Sykes is in favor of the large dose of quinin given in solution. The cases in which the best results were obtained were treated as follows: First week, 20 grains of quinin sulphate were given daily, four hours before the expected attack. Second week, the dose of quinin was reduced to 17.5 grains. Third week, the dose of quinin was reduced to 15 grains. The patients were kept in bed the first week; allowed up half day the second week, and all day the third week, with physical exercises and route marches. All the cases were of old standing, the duration of the disease varying from eight months to two years and eight months, and they were all cases of undoubted malaria Relapses have occurred in only 25 per cent.

45. **Zinc Treatment of Cold Abscess.**—Sztark has found exceptionally effectual the application of a sheet of zinc, the thinnest possible, cut to fit the shape of the lesion and applied directly to it. He explains its action as the result of the ions generated by the different nascent compounds of zinc. The metal is held in place with a dressing which is left undisturbed for five or seven days. Any tendency to hypertrophy of the edges of the lesion calls for cauterization. He reports that long rebellious cold abscesses yielded promptly to this treatment.

48 Mechanism of Prostatic Retention of Urine. F. Legueu.—p. 458.

46. **Grafts of Dead Tendons.**—The Journal mentioned recently in these columns, page 149, the results obtained in a hand that had had six strips of dog tendons introduced to bridge extensive gaps in the tendons. Fine functional results were realized. Delorme has reexamined the man recently and found that practically the complete use of the hand had been regained, the dead animal tendons, which had been kept in alcohol for a month, acting like normal natural tendons. He urges the application of this technic on a large scale to aid men who have lost the use of one or more fingers from destruction of tendon substance.

Bulletins de la Société Médicale des Hôpitaux, Paris

Oct. 18, 1918, **42,** No. 29

49 *Influenza. Florand.—p. 949; Caussade.—p. 954; Rénon and Mignot. —p. 958.
50 *Pfeiffer's Bacillus in Influenza. Orticoni and Barbié.—p. 959.
51 Form of Colloidal Gold in Influenza. A. de Verbizier.—p. 961.

53 Follicular Psorospermosis. L. Giroux and Miriel.—p. 966.
54 *Malaria and Wassermann Reaction. Aimé and Lochelongue.—p. 968.

49. **Influenza.**—Florand's experience with 500 cases has convinced him that one attack usually confers immunity after complete recovery. The rarity of otitis, sinusitis and mastoi- ditis is noticeable, as also the almost constant tendency to hemorrhages. Spirochetes are frequently found in the sputum, but no one ascribes pathogenic importance to them. Netter thinks that plain serum would probably be as effectual as the antiserums that are being used, and if plain beef serum were used, it would ward off any tendency to anaphylaxis later. Caussade comments on the toxemia with influenza, saying that all treatment will fail until we definitely identify the pathogenic agent of the disease and institute specific serotherapy. The only rational treatment to date, he reiterates, is with antipneumococcus serum in the cases in which the pneumococcus is involved.

50. **Pfeiffer's Bacillus in Influenza.**—This report states that the influenza bacillus was cultivated from the blood, the pleural fluid or the cerebrospinal fluid in 58 per cent. of ninety cases. About 200 c.c. of glucosed bouillon is inoculated with 10 or 15 c.c. of blood taken from a vein of a patient with temperature of 102 or 104 F. Other germs add their action, but the Pfeiffer bacillus seems the pioneer. But it may be merely the pioneer of the second invasion, the first being by a still unknown germ.

54. **The Wassermann Reaction in Malaria.**—Aimé warns that a positive Bordet-Wassermann reaction should not be accepted as necessarily a sign of syphilis unless malaria, possibly atypical, can be excluded. In case of doubt, give quinin and watch the response then to the Wassermann test.

57 Mosquitoes and Old Foci of Malaria in the Mountainous Regions of Southeastern France. L. Léger and G. Mouriquand.—p. 524.

55. **Artificial Anus.**—Guérin reviews the experiences in Delore's service with eighteen cases of a stercoral fistula or artificial anus. In nine of the cases lateral enterorrhaphy answered the purpose perfectly, the patients being all completely cured of their abnormal anus in less than a month. In the other cases enterectomy was required and proved equally successful. The dangers of this operation have been exaggerated, he emphasizes; it always proceeded smoothly in the cases reported. The only case in either series in which an attempt was made to operate extraperitoneally, proved a failure, and the intraperitoneal technic had to be applied after all. The eighteen cases are described in full, with the details of the technic.

56. **Propagation of Pericardium Friction Sounds.**—As a rule, the pericardium friction sounds do not spread. But occasionally, with the pericarditis of Bright's disease, the friction sounds are heard at a distance and two cases are on record in which it occurred with rheumatismal pericarditis. Teissier here reports a case in which the friction sounds were heard over a remarkably large area, and necropsy showed all the organs in the thorax soldered together from tuberculous pericarditis.

61 *Septicemias. P. Govaerts.—p. 597.
62 *Blood Pressure in Malaria. E. Jeanselme and R. Dalimier.—p. 599.
63 Fracture of Ascending Ramus of Lower Jaw; Diagnosis and Treatment. L. Imbert and P. Réal.—p. 601.
64 Edema with Liver Disease. Editorial.—p. 603.
65 *Disinfection of Cavities. J. Silhol.—p. 604.

61. **Significance of Septicemia.**—Govaerts remarks that Bull has thrown much light on the nature of septicemia by his discovery that certain bacteria become agglutinated at once when injected into the blood of an experimental animal, and the bacteria disappear from the blood. The outcome of the infection thus depends on whether or not the animal's blood has a natural or acquired agglutinating property, as the bacteria, once agglutinated, become rapidly incorporated by the phagocytes. Govaerts has continued research in this line and here announces that the phenomenon is not actual agglutination, such as we see in the test tube, the bacteria sticking together. In the animal's blood, on the other hand, the bacteria become involved in a mass of blood platelets which solders them into a more or less solid mass without the bacteria themselves sticking together—there are always interposed platelets between them. This action of the platelets is elective, he adds, because when an emulsion of staphylococci and of pneumococci, mixed, is injected into the blood, the platelets pick out and solder the pneumococci while the staphylococci are left floating free in the blood. The agglomerated masses are arrested in the capillaries and they rapidly disappear, the bacteria vanishing as they are phagocyted. He is unable to state positively the fate of the platelets involved. If virulent pneumococci are injected into the blood of a rabbit, they do not become agglutinated in this way but keep on floating free in the blood stream. The same pneumococci, injected into the dog, rapidly mix with the blood platelets and become agglomerated in masses, vanishing from the blood stream. His research suggests that a phagocytic action must be attributed to the platelets, and that the ability to induce septicemia is not a question of the virulence or nonvirulence of a strain of bacteria but is a matter of their stability in the blood stream, their power of resistance to the agglomerating force of the platelets. The intensity of the septicemia depends, of course, on the power of the bacteria floating free in the stream to multiply. This power is possessed in high degree by the streptococcus, to a lesser extent by the staphylococcus, and by the perfringens or gas bacilius. Resistance to agglutination, resistance to phagocytosis, and aptitude for inducing septicemia seem to be all three the result of some special physical condition of the surface of the microbe.

This brings up the new question why at a given moment the bacteria of a hitherto localized infection suddenly acquire properties which permit them then to escape agglutination and circulate freely in the blood stream. This brings the question how to modify the surface of the microbe floating freely in the blood stream so that it will stick to the platelets and become agglomerated in masses of them. It seems logical to try to accomplish this by injection of an agglutinating serum; this might be tried in typhoid septicemia. In surgical septicemia the difficulty would be to obtain an agglutinating serum that would act on the different strains of streptococci, etc., involved. It is by an analogous action that Hooker's success with transfusion of immunized blood can be explained. The donor is first vaccinated by means of a microbe cultivated from the blood of the septicemia patient. It is evidently by some modification of the surface conditions of the microbes in the blood stream that the colloidal metals, foreign proteins, etc., exert their influence in treatment of septicemia. It has been noticed that all these diverse substances that have proved more or less effectual in treatment of septicemia, cause agglomeration of the platelets. The chemical composition of the substance injected into the blood seems of less import than its physical properties, but hitherto this phase of the subject has not been studied. As the mechanism of their action has not been understood before, it was impossible to select them with intelligence or gage their efficacy beforehand.

62. **The Blood Pressure in Secondary Malaria.**—The maximal arterial tension in ordinary malaria past the acute phase keeps at a certain level all the time, but the minimal tension varies within a remarkably wide range with every attack. This shows that the myocardium is clinically sound while the vascular tension fluctuates to a remarkable extent. The discovery of a drop in the maximal tension thus should warn that the malaria is passing into a pernicious phase or the heart is showing signs of weakening. The suprarenals seem to suffer during the malarial attack, and this may be the explanation of the upset in the vascular tension, the suprarenals either functioning to excess or becoming insufficient.

65. **Disinfection of Cavities in War and Peace.**—Silhol remarks that he used to rinse out the pleura but usually had deplorable results. The war has shown that the principle is correct but that it must be applied with infinite attention to details. This makes it a life-saving and promptly effectual measure. The same can be said of irrigating the infected uterus. In a recent case the puerperal uterus was profoundly infected, the cervix soft, the young woman's general condition grave, but there was no albumin in the urine, and Silhol had Carrel's method of irrigation applied to the uterus by a nurse skilled in the technic. The temperature began to go down by the next day and in four was normal. Contrary to his advice, the Carrel irrigation was suspended as soon as the acute phase was past, and a few weeks later symptoms of salpingitis became apparent. He is convinced that Carrel treatment kept up long enough would ward off infectious processes in the adnexa, especially when begun early. The lessons learned in war surgery in regard to disinfection of cavities should be applied in civilian practice without delay.

70 Treatment of War Wounds. G. Louvard.—p. 215.
71 Femoral Arteriovenous Aneurysm. M. Haller.—p. 217.

66. **War Suprarenal Insufficiency.**—Satre and Gros give a number of examples of what they call war hypoepinephric

syndromes. Supplying the lacking epinephrin cured the disturbances when they took the form of a diarrhea resembling cholera, as also in grave gastro-intestinal toxic infections. The men thus affected had led a sedentary life before the war, and the functioning of their damaged suprarenals had sufficed for their regular indoor life, but under the stress of campaigning the insufficiency of their endocrine system soon made itself manifest. The symptoms reveal the inability of the antitoxic functions to cope with the excessive amounts of poisons generated by the waste from muscular work. Whether there is merely functional suprarenal upset or organic damage, the fundamental symptoms are the same, vomiting, dizziness, asthenia and hypotension—just as in seasickness. There may be also small brownish spots on the skin, symmetrically distributed. When the solar plexus is irritated, there are liable to be apoplectiform coma or pseudomeningitic symptoms, vasomotor disturbances, etc. The blood pressure is low in all the forms. Arsenic, mercury and iodid are violent poisons for the suprarenals; nicotin is also injurious for them. Large and fractioned doses of epinephrin are called for, with ingestion of the total extract of the suprarenals. The epinephrin and extract of the capsule have a tonic and cardiovascular action, remarkably effectual, promptly raising the blood pressure and acting energetically to promote diuresis. If the epinephrin can be given by the mouth, from 8 to 10 mg. can be taken during the twenty-four hours, fractioned and well distributed. It should never be given in syrup, but the drops should be counted into sweetened water just as the dose is to be taken. The digestive intolerance usually makes it necessary to give the epinephrin by intramuscular injection.

69. **Poliomesocephalitis.**—This term is used to express what Netter and others call lethargic encephalitis. Two absolutely typical cases are described; high fever, narcolepsy and ptosis are the main features of the disease.

Revue Médicale de la Suisse Romande, Geneva

November, 1918, **38**, No. 11

72 *Influenza. N. Betchov.—p. 625: J. Minkine.—p. 634.
73 *Poisoning from Barbital. P. Gautier.—p. 641.
74 Influenzal Albuminuria in Children A. D'Espine.—p. 647.
75 Ileus from Cherry Stones. Mauclaire.—p. 651.

72. **Influenza.**—Betchov expatiates on the characteristic fever curve in influenza, with its two high peaks at a two or three day interval, and the exacerbation of symptoms which parallel these double peaks. He thinks that this double course is explained best by the assumption of a multiple virus, twofold at least. The first virus must be a filtrable inframicroscopic substance which traverses countries with a rapidity without an equal in the annals of epidemiology. The second peak is the work of ordinary germs, especially the pneumococcus, which follow in the wake of the first virus. The incubation was exactly two days in his experience, and contagion seemed to occur only during the early catarrhal phase, before the subject felt that he was really sick. He is inclined to regard the characteristic pain in the spine region as the result of congestion and hyperfunctioning of the suprarenals. Minkine declares that influenza always confers a relative and usually a permanent immunity. It never exists in epidemic form in a country with rapid and multiple means of communication, and he insists further that it is possible to arrest an epidemic. A mask or handkerchief covering mouth and nose while in the room with the sick is effectual protection if the hands are washed often.

He exclaims that if a man does not open his umbrella until he has walked several minutes in a shower, the fact that he is wet does not prove that the umbrella does not protect against the rain. Contagion is always by direct immediate contact with some-one with influenza. In spite of extensive investigation, he has been unable to discover an instance of transmission of the disease by fomites. The pandemics are due to the fact that influenza is transmitted only slowly from place to place in remote regions with rare and slow means of communication. When it reaches railroads and other rapid means of communication, and the virulence of the virus becomes enhanced by repeated passages through human beings, it spreads more and more rapidly and with greater virulence. The concentration of men in camps this year provided exceptionally favorable conditions for its rapid and universal spread, as a new generation had arisen unprotected by immunity. The human race would die out, he remarks, if there were even one pandemic which did not confer at least a transient immunity. Epidemic influenza exists in sporadic form in the unpeopled regions of Turkestan and perhaps in the heart of Africa.

He says that the influenza virus does not exist in an active phase in the external world; this assumption is based on the single but well established fact that in every case direct contagion can be demonstrated if sought with enough care. The persons to tend influenza patients should be selected among those who have had the disease. They will not contract or spread it. All gatherings in enclosed places should be forbidden, and the cafés in particular closed, and persons obliged to work in common should be compelled to wear a mask. These precautionary measures need not be kept up long; a period of two weeks is ample. Draconian measures applied for a short period are effectual; half-way measures, even long kept up, are of no use whatever. Both Betchov and Minkine have had practical illustration of the principles they advocate as the isolated sanatoriums of Switzerland provided conditions as in a laboratory experiment.

73. **Barbital Poisoning.**—Gautier reports four cases of self-drugging or attempt at suicide in which 3.5, 5, 7 or 8 gm. of diethyl malonyl urea had been taken. One woman of 33 died after four days of coma and hyperpyrexia; the dose had been only 5 gm. Necropsy revealed nothing but congestion of the brain and the bases of both lungs. Those taking this drug habitually seem less able to stand moderate doses than others. Death has occurred from a 3 gm. dose in the addicts while recoveries are known after a single dose of 10 gm. Treatment can be only symptomatic. Gautier protests against the unrestricted sale of barbital, particularly as it is liable to lead to morphin addiction.

80 *Recklinghausen's Disease. A. Roccavilla.—p. 321.
81 *Nitrobenzene Poisoning. P. Zuccola.—p. 341.
82 *Antitetanus Serum Neutralizes Strychnin. A. Londini.—p. 351.

76. **Epidemic Meningitis.**—Brignone emphasizes that with large and repeated doses of antimeningococcus serum and isolation of the sick and contacts the physician even in the remotest village can feel that he has no cause to dread epidemic meningitis more than any other disease, and that he can defend his patients against it. As a rule, he says, a polyvalent antiserum should be given the preference. The room should be disinfected, and for this he advises calcimining the walls; a hot 10 per cent. solution of soda for the floors, and the steam sterilizer—the autoclave—for the clothing and bedding, or else boiling. The contacts should be relatively isolated for two or three weeks, and the throat and nose examined every day and the tonsils painted with a 3 per cent. iodized glycerin with antiseptic gargles, and the nose douched with potassium permanganate and a mentholated salve applied inside the nose. These measures should be supplemented by a subcutaneous injection of 20 c.c. of antimeningococcus serum as a preventive given to those most exposed to contagion. Preventive vaccination is said to confer durable immunity, but he does not seem to have had personal experience with it. The curative dose of the antiserum ranges from 30 to 50 c.c. for intraspinal injection after withdrawal of spinal fluid in amounts a little more than the serum injected. The dose for infants is from 10 to 20 c.c. He has lost only two of his thirteen patients and these were in the last stages of the disease when the physician was first summoned. When the serotherapy was begun by the second day, the prompt turn for the better was constant.

80. **Neurofibromatosis.**—Roccavilla gives a minute description of two cases of Recklinghausen's disease, both in sol-

diers. He tabulates the metabolic findings and appends the biography of the last five years. There was nothing to suggest toxic action in the antecedents, no tuberculosis, syphilis, or other severe infectious disease, but the data presented seem to justify the conception of the endocrine-sympathetic nature of neurofibromatosis.

81. **Nitrobenzene Poisoning.**—Zuccola reports that a woman of 41 drank by mistake one morning, fasting, 30 c.c. of nitrobenzene (oil of mirbane). Emetics were administered in a few minutes after the first symptoms and she vomited, and in three quarters of an hour the stomach was profusely rinsed out and stimulants were injected. At the end of an hour and a half the woman sank into coma. The poison displayed a most rapid and intense destructive action on the blood, but this was followed by extremely active regeneration of the blood. Bone marrow obtained by trephining a rib and the tibia showed intense hyperactivity. Animals experimentally poisoned with nitrobenzene did not show any changes in the blood remotely resembling those in his patient, whose capacity for reaction was remarkable. At first the tint of the face was blackish, the subcutaneous veins looked like black stripes, and the limbs were contracted, with jerky movements, trismus and opisthotonos; the pupil reflexes were abolished as well as control of the sphincters. Blood from the finger looked black, and the reds did not form coin rolls. About 400 c.c. of defibrinated blood were injected into a vein after a few hours, and marked improvement followed. The transfusion was repeated two days later and the woman was discharged in good condition the fortieth day. The blood findings from day to day are recorded. The anisocytosis was most impressive. Some of the reds measured 14 and even 16 microns, while others measured only 2. The dark tint of the skin persisted for nearly two months. The blood findings and the clinical course resembled those in Pollak's case of acute copper sulphate poisoning.

82. **Power of Antitetanus Serum to Annul Toxic Action of Strychnin.**—This property of antitetanus serum has proved useful in standardizing the serum. Londini here presents evidence to show that this property is dependent on the cholesterol content of the antiserum. With cholesterol alone, the toxic action of strychnin can be annulled. The antistrychnin action seems to be proportional to the cholesterol content of the antiserum, but does not seem to have any connection with the antitoxic property of the antiserum.

Riforma Medica, Naples

83 *Mechanism of Action of Chloroform. V. Aloi.—p. 890.
84 *Mercuric Chlorid in Influenza. G. Ferrarini.—p. 893.
85 Postdiphtheric Stenosis of Larynx and Trachea. D. Tanturri.—p. 894.
86 Referendum on Influenza. Centanni and others.—p. 896.

83. **Action of Chloroform.**—Aloi reports research the results of which seem to confirm the increase in the urea, ammonia and total nitrogen in the urine after chloroform anesthesia. In small doses, no appreciable anatomic damage results, but with prolonged administration and large doses, grave changes develop in the organs, an actual fatty degeneration, mainly in the heart, the liver, the kidneys. Diabetes induces lesions analogous to those from chloroform, a clinical picture resulting under chloroform which resembles the acidosis of diabetes. He was able to determine directly the presence of beta-oxybutyric acid in the urine, in eleven cases described, as the immediate result of inhalation of chloroform. In one case of the kind, 25 gm. of choloroform had been used in a hemorrhoid operation, and afterward the total nitrogen rose to 18.732 per thousand, with beta-oxybutyric acid, but no acetone. In most of the other cases there was abundant acetone for a time.

84. **Intravenous Injection of Mercuric Chlorid in Treatment of Influenza.**—Ferrarini advocates in grave cases of influenza a daily intravenous injection of 0.01 gm. mercuric chlorid dissolved in 1 c.c. of physiologic saline. This gave such good results in his experience with hundreds of cases that he has abandoned all other measures except heart tonics when needed. He has never had any untoward by-effects with these large doses, and even grave albuminuria does not contraindicate this treatment; it improves instead of growing worse under it. He begins this treatment at the first sign of congestion of the lung, but even at the fifth or seventh day it proved effectual in a large number of cases, patients recovering under it who previously had seemed doomed.

89 *Reconstruction of Eyelid. Soria y Escudero.—p. 129.
90 *Mercuric Chlorid in Puerperal Fever. J. A. Pérez.—p. 130.
91 *Stenosis of Esophagus. A. Torres y Lopez.—p. 133.

89. **Reconstruction of Eyelid.**—Soria cut a long flap of skin extending down below the ear, according to Snydacker's technic, and twisted it around to make the new eyelid. The lid had been destroyed by a malignant pustule at the age of 14. It had been treated with the actual cautery and the retraction of the tissues left the eyeball exposed. The photographs show the apparently complete success of the blepharoplastics.

90. **Mercurial Treatment of Puerperal Septicemia.**—Pérez relates that he gives intravenous injections of a 1 per thousand solution of mercuric chlorid in treatment of puerperal septicemia. He has thus treated 200 patients, giving 2 c.c. the first day, half in the morning and half at night; the second day 4 c.c., fractioned, and so on up to 10 c.c. the fifth day, continuing with this dose, until the fever drops, then keeping on with half the dose. The curative effect is most pronounced in the cases of pure septicemia. In the fulminating cases the organism does not have time to react, and these injections are contraindicated, as also in pyemia. No by-effects of any importance were observed in any instance, while recovery occurred under this treatment in large numbers of otherwise apparently hopeless cases. Physiologic serum is specified as the vehicle.

91. **Stenosis of Esophagus.**—Torres comments on the remarkable prevalence of esophagus disturbances in his district (Granada). In a recent eight months there were thirty-one cases of stenosis at the clinic or in his private practice, and he here gives the details of this series. The roentgen rays show a large diverticulum in some. Most of the patients were men from 40 to 60 but one was a young man of 18. In all, the disturbances had come on gradually after symptoms on the part of the stomach for a long time, and in several cases other members of the family had likewise had stomach and esophagus trouble. In only one of the total thirty-one cases was the stenosis the result of drinking a caustic; this was a girl of 5 who had drunk hydrochloric acid five months before. No mention is made of the treatment in any case.

94 Obstetric Puericulture. M. Acuña.—p. 140.
95 *Protection of Duodenal Stump. N. Tagliavacche.—p. 145.

92. **Drainage of the Peritoneum.**—Finochietto gives five illustrations to show the different types of drainage required for various abdominal processes, and urges a combination of aspiration and intermittent irrigation as particularly useful in certain conditions. The aid of gravity must be utilized to the utmost, as he shows in detail. It may be necessary to drain the recesses of the mesentery, and for this he passes two tubes through from one flank to the other, passing one through a hole in the mesentery near the spine. One tube is for the irrigation, the other for the draining.

95. **To Protect Stump of Duodenum.**—Tagliavacche refers to the stump left after pylorectomy when the benign lesions in the anterior portion of the pylorus and duodenum do not involve the posterior portion of the initial segment of the duodenum. When the pyloric segment of the stomach is cut off, he turns it back on itself like a barn door which brings into view the peritonized posterior aspect of this pyloric segment. He cuts a flap in the peritoneum at this point, its

hinge portion on a level with the duodenum and pancreas. After resection of the pylorus, this flap is used to make a staunch covering for the duodenal stump, with a special triple row of sutures, as he shows in six illustrations of this *peritonco-duodenoplastia,* as he calls it.

96. **Prophylaxis of Serum Sickness with Beef Serum.**—Penna, Cuenca and Kraus have found that beef serum injected before or with horse serum seems to neutralize the tendency of the latter to induce serum sickness. They describe the various efforts that have been made to ward off phenomena of anaphylaxis, and relate that the Besredka method of preliminary injection of a very small dose, a few hours before the main injection, has proved almost invariably effectual in animals, but it fails occasionally in the human, as they have experienced again and again with diphtheria antitoxin and antitetanus antiserum. No method to date has fulfilled the anticipations of its discoverer, so that the problem of prophylaxis of serum sickness is still clamoring for solution. In their extensive experience with normal beef serum in treatment of anthrax, they became convinced that beef serum may solve the problem. Their success in reducing the mortality of anthrax to a lower figure than ever before recorded, using plain normal beef serum in treatment, was accompanied by a notable reduction in the proportion of cases in which serum sickness developed, notwithstanding the large doses of normal beef serum injected. Further experiments with cattle have demonstrated that potent diphtheria antitoxin and antitetanus serum could be obtained with beef serum as well as with horse serum. With these antiserums there need be no fear of anaphylaxis on suspicion of a preceding serotherapy. By using beef antiserum, all danger is averted. Some recent experiences at the Children's Hospital have confirmed that serum sickness occurs only exceptionally (2.1 per cent. in 290 cases of anthrax; 0 in 40 cases of typhoid), when beef serum is injected, normal serum or as a diphtheria or tetanus antiserum. Given in equal quantities or at least over a third, with horse antiserums, it materially reduces the tendency to serum sickness (12.7 per cent. in 33 cases of typhoid or anthrax).

97. **Treatment of Whooping Cough.**—Barilari reports attempts at treatment of whooping cough with the patient's own sputum, or with asthma sputum, with an autovaccine, with sputum from healthy persons, and with various preparations. Charts are given showing the abrupt drop in the number of paroxysms after injection of an autovaccine or a preparation made from the patient's sputum. The latter is generally called Kraus' antitosina. One young man with violent paroxysms and vomiting, the tenth day of the disease, was improved by a single injection of autovaccine, no vomiting occurring thereafter. The second injection two days later was followed by a drop from twenty to eight paroxysms a day, all immeasurably milder, in less than a week. A young woman with whooping cough for a month was given two injections of 5 c.c. of a preparation from whooping cough sputum, and in a week the paroxysms had dropped from twenty-eight to nine, much less severe. No effect was apparent in some cases, but, on the whole, Barilari extols this antitosina method as efficient. The sputum for the antitosina must be from persons who have not previously been treated with it. The cough loosens up and becomes less spasmodic, and vomiting ceases. Thirteen charts are given; they demonstrate the superior efficacy of this whooping cough sputum therapy, at least over the other substances tested.

98. **Production of Antitoxic Serums.**—The Journal has previously mentioned (May 11, 1918, p. 1406), the success of Kraus and Sordelli in producing in a remarkably short time an exceptionally potent diphtheria antitoxin by injecting a neutralized mixture of diphtheria toxin and antitoxin, nonfatal for guinea-pigs. Sordelli here reports further experiences in this line which have confirmed the previous statements. In both old and young horses an antitoxin was obtained in two months far surpassing what could be obtained by the usual toxin method of immunization in five months. In one horse, an antitoxin potency of 1,200 units was obtained in two months, in two others, of 220 and 450 units. These three horses were under 5. With the older ones a potency of 700, 600, 180 units was obtained in about two months. Antitetanus serum was obtained in the same way by immunizing the horses with a mixture of tetanus toxin and antitetanus serum. The results were quite favorable, a potency of 150 and 250 units being realized in four or five months such as usually takes eight months to realize. More striking results were obtained when, instead of this, the horses were treated with tetanus toxin the toxicity of which had been annulled by addition of formaldehyd, 1.5 per thousand of the 40 per cent. solution. This toxoid proved nonfatal for guinea-pigs after a few days of contact, none of the animals dying by the eleventh day of contact when injected with 3 or 5 c.c. The antitoxic potency of the serum of horses immunized with this toxoid surpassed anything hitherto known in this line, two horses reaching 1,500 units in six or seven months, although they were 14 and 15 years old and were in poor condition at the start. Good results were obtained also with horses that had been previously immunized with the pure toxin.

99. **Race and Family in Transmission of Cancers.**—Roffo reports several series of experiments with transmission of cancers in white rats, one series alone using 1,150 animals. By interbreeding with the common black rat, and other experiments, he was impressed with the constant predominance of the mendelian laws of heredity as manifested in susceptibility to inoculated cancers. A difference in race and family, even a change to another environment, modifies the receptivity.

100. **Vaccination Against Anthrax.**—Rossello describes an antianthrax vaccine now made in Uruguay. It is a uniform emulsion of a certain number of free spores, and confers a more durable immunity than vaccines made from the bacteria themselves.

101. **Research on Snake Venoms.**—The diastasic properties of the organs of the *Lachesis alternatus* were investigated by Houssay and Negrete, as here reported. Another, their fourth communication on snake venoms is devoted to some Australian and East Indian snakes.

102. **Anaphylatoxins.**—The results of experiments on one species of animals cannot be applied to other species or to man without discrimination. The researches here reported confirm this fact anew, showing how a bacterial anaphylatoxin prepared with guinea-pig or rat serum is extremely toxic for guinea-pigs but not for rats and rabbits. On the other hand, anaphylatoxin prepared with rabbit, horse or dog serum does not seem to be at all toxic for guinea-pigs nor for the rabbit, horse or dog.

107 The Liga Contra la Tuberculosis. C. Alvarez.—p. 415.

104. **Treatment of Chronic Metritis.**—Argons insists that when there is cervicitis we can count on there being also metritis. The two can be cured, he says, in the simplest and easiest way by cauterizing with Filhos' caustic. This, he says, is a mixture of 2 parts potassium hydroxid and one of lime (*potasa caustica y cal*). The mixture is liquefied and run into the shape of a pencil. With this the lesions are cauterized. They form a soft black eschar, which drops off in eight or ten days not leaving a retractile cicatrix. The pain induced by the cauterization was insignificant in the six or seven cases thus treated. In two of them, described in detail, the metritis was of long standing and surgical

measures seemed the only resource. The caustic of Filhos is one of the old formulas in the textbooks as a paste made of caustic potash and quicklime mixed with alcohol. The French Codex specifies: potassa 100, lime 20; melt the potassa, add the lime and pour into molds.

109 *The Law Regulating Septic Accumulations in Otology. F. Rueda. —p. 99. Commenced in No. 1527, p. 65.

109. The Law of Narrow Passages.—Rueda says that the middle ear represents a diverticulum of the respiratory apparatus. The eustachian tube grows very narrow as it ascends, and this narrow portion is an important protection against the migration of germs from the mouth to the middle ear. In case of inflammation, the narrow portion becomes congested and may close up entirely for the time being, thus protecting the ear completely. But if the germs manage to get into the ear, the very fact of the narrowness of the passage into the tube prevents ample drainage. The bacterial products accumulate; as they are unable to escape they damage the walls of the cavity, and these walls lose what defensive powers they normally possessed, while the germs in the enclosed space have their virulence enhanced. He shows how the whole middle ear and mastoid apparatus is a succession of narrow passages and broad cavities which all act in the same way to check the spread of infection, but once it has passed the barriers, it acquires unwonted virulence. His diagram of the conditions shows further how the infection can spread along a narrow passage and cause no damage to the walls or have its virulence increased, but when it reaches a cavity where the pus can stagnate, then serious processes develop at this point, and the infection seems to have leaped over the intervening space.

110. The Tuberculin Test in Children.—Garrahan and Iraola applied to 350 children the tuberculin *skin* test, the intradermal and the puncture test, using, respectively, the Pirquet, the Mantoux and the Hamburger technics. The children were from 2 to 13 years old, and all were apparently healthy. More than 1,500 tuberculin tests were made in the course of this research. They compare their findings with those recently reported by Bass. They confirm the greater sensitiveness of the Mantoux intradermal technic (with 0.0001 gm. tuberculin). It was often positive with a negative Pirquet, sometimes even in cases of active tuberculosis. There were no mishaps from the intradermal test; the one case of ulceration followed the skin test. The necessity for repeating the tests is greater the older the child. From 11 to 14 the skin tuberculin test at the first application gave only 55 per cent. of the positive responses obtained on repeating the test. No harm seemed to follow the intradermal or subcutaneous injection of the larger dose, 0.001 gm. tuberculin, when the response before had been negative or dubious.

114. Boiling of Milk.—D'Alessandro protests that if we systematically boil milk for children we must boil the butter also.

117. Sign of Death of Fetus.—Gandolfo's experience has confirmed the value of Boero's sign of the death of the fetus. When the beat of the aorta can be heard through the uterus between the fourth and seventh months of a pregnancy, the probabilities are that the fetus has been dead for at least ten or fifteen days. The beat of the aorta is not heard with the stethoscope in normal gestation at this period. In his experience, this sign never failed to be a reliable index of the death of the fetus.

Siglo Medico, Madrid

123 Significance and Origin of Rieder's Cells. G. Pittaluga.—p. 794.
124 Referendum on Influenza. M. Salazar and others.—p. 796.

120. Symptoms from Bladder Stones.—Martin remarks that the first symptom from the presence of a stone in the bladder is increased frequency of micturition after exercise liable to displace the stone in the bladder. Each new contact of the stone with the walls of the bladder acts as a foreign-body stimulus for the bladder to contract. Inquiry will usually elicit this increased frequency of micturition after exercise, although the patient may not have heeded it. The questions must be worded so as not to suggest the answers to the patient. Twelve cases are described; one boy of 12 complained of a sensation as of a foreign body in his bladder, and it hurt him when he ran or jumped. Another boy of 14 had for years had difficulty in urinating. After each micturition he had to remain seated for a time as standing was extremely painful. He was unable to run or ride a horse on account of the pain. Drinking water also induced pains by the resulting distention of the bladder.

Pain with stones in the noninfected bladder seems to grow less with increasing age. Especially in prostatics, the presence of a stone may cause no appreciable disturbances whatever. A boy may obtain relief from the pain with a stone by pulling on the bladder. He may tear a hole in his breeches pocket in order to do this. A transient interruption of the jet of urine is also instructive, but it is not always a sign of interposition of a stone. Simple cystitis may induce it by the spasm from the pain. Hematuria following exercise and disappearing or diminishing with repose is a symptom of capital importance, even when slight and infrequent. It can be rendered manifest by setting the patient at vigorous exercise, comparing the urine before and after. One man of 64 had blood in the urine when he coughed much. Stones in the kidney, ureter and urethra are not so movable as in the bladder, and hence exercise does not affect the pain from them as a rule. Incontinence of urine may also be a sign of a bladder stone. In three cases reported, the incontinence subsided after removal of the stone. In another case the symptoms were contradictory. There was pain at micturition, most pronounced during repose in bed, and there was no pain when the boy of 13 was running. Terminal hematuria had been noted on two occasions, and occasionally interruption of the jet. One man of 75 who had been under treatment for acute gonorrhea had persisting turbid urine, and the cystoscope disclosed two large bladder stones although there had never been previously any symptoms from them. In most of the cases described lithotrity proved all that was necessary, even in the boys of 12 and 14; when this was impossible prompt recovery followed the high incision.

125. Alternating Rhythm.—De Boer gives electrocardiograms of alternating rhythm on the part of the ventricle, especially when the heart was under the influence of digitalis and antiarin. His tracings throw light also on the origin of ventricle alternans from delay in transmission of the impulse.

126. **The Physicians of Ancient Egypt.**—De Lint describes the tombs of some of the leading physicians of ancient Egypt, who evidently were prominent men in their day. He also quotes from Herodotus to illustrate the high position they held as medical men and priests. The wall pictures of the tomb of Sechemet, dating from the dynasty 2750 to 1625 B. C. show a luxuriant growth of hair, but those of Auta, a physician during the dynasty that reigned 1350-1205 B. C., are completely shaven, and Herodotus says that the physicians had to shave their entire body every three days. De Lint ascribes this to protection against vermin. Even the eyebrows were shaved off, and they were compelled to bathe twice during the day and twice at night. Their diet was regulated to exclude indigestible articles; they were forbidden to eat beans and pork. They were supported by the offerings made to the gods and had no financial cares. The fees paid by patients could be laid aside for their old age. Polygamy was forbidden to the physician priests. De Lint describes some statues of physicians, preserved at Petrograd and at Leiden, which bear inscriptions to the effect that the offerings made to the gods are to be saved for the physicians, and some of the pictures on the walls of the tombs show the physician and his wife seated at the table of offerings.

127. **Prophylaxis of Infectious Diseases.**—At certain times during the war the children of Reims were compelled to wear gas masks to school. Mees says that he saw recently a photograph of a school room there in which all the children were thus wearing gas masks. If this could be enforced against gas bombs, there is no reason, he declares, why children could not be compelled to wear masks to protect them in times of epidemic disease. In the streets it might not be necessary and would be hard to enforce, but in the school room, under the teacher's eye, it would be a comparatively easy matter thus to ensure absolute protection of the children by this means during the school hours. He suggests that a trial might be made in some small town where diphtheria, for example, seems to be endemic and recurs year after year. If the wearing of masks during school hours was followed by the disappearance of diphtheria from the town, we would know what to think of this prophylactic measure. He mentions several towns in the Netherlands peculiarly adapted for this experiment on a large scale. The children from homes where there is already sickness, and the known carriers might be compelled to wear the masks all the time they are away from home.

129. **Cancer at Amsterdam.**—De Vries relates that at the University Institute of Pathology during the last seven years there have been 518 cases of cancer found among 3,700 necropsies, that is, in 14 per cent. of all the cadavers. Of those under the age of 40, cancer was found in only 2 per cent. The youngest was in a man of 21, cancer of the liver; a woman of 22, rectum, and a man of 23, colon. Cancer of the alimentary canal, from mouth to rectum, formed four fifths of the total; the stomach, two fifths. The institute does not get many female cadavers, which explains the small number of uterine cancer cases. In eighty-two cases the cancer had not been diagnosed during life, often because it was masked by the other fatal disease. This proportion of 16 per cent. of unrecognized cases shows that the official records must be usually too low. In ten cases there were two or more cancers, both evidently primary, but in ten other cases the microscopic findings in the two or more tumors were so much alike that only one in each case can be considered as primary. In conclusion, a series of similar statistics from nine other institutions of the kind are tabulated for comparison. Two from Switzerland show thirty-four and twenty-nine cases of cancer of the thyroid in 521 and 1,078 cadavers. In the other countries there were only from one to five thyroid cancers, and only seventeen in all among the eight other series of statistics, from the Netherlands, Germany and Austria. There was a total of 175 cases of cancer of the lungs among the total 5,795 cadavers listed.

130. **Starch Grains in the Fasting Stomach.**—Wijnhausen and Lubbers report the findings in 600 persons whose stomach content was examined in the morning, fasting, after a test supper of two slices of bread and butter, nine hours before, the mouth well rinsed afterward. It always proved possible to aspirate 1 or 2 c.c. of mucus and fluid from the fasting stomach, and in a certain number of cases grains of starch were evident in it. When no grains of starch could be detected with the naked eye, it was sometimes possible to discover some with the microscope. They classify the cases as those with no microscopic starch grains; those with 1 or more widely scattered grains; those with 1 grain in each field; those with several in each field, and those with macroscopic minimum retention.

The tabulated findings in the 600 cases show that only the gastric and duodenal ulcers were represented in the class *c*, up to 20.6, 22.8 and 23.9 per cent. of the ulcer cases being found with macroscopic minimum retention. On the other hand, all the gastric cancer cases and the cases of gastric achylia were exclusively in classes *a* and *b*, 90 per cent. of each showing no grains of starch under the microscope, and 10 per cent., showing only one or more widely scattered grains. In these two classes were found also all the persons free from any symptoms on the part of the stomach. With stomach disturbances from gallstones, with atony of the stomach, with gastroptosis and with hyperacidity and gastric neuroses, the proportions of cases in class *c*, that is, with macroscopic minimum retention, were, respectively, 8.3, 6.7, 4.5 and 2.6 per cent. From 9.1 to 45.7 per cent. of the entire 600 tested, including the healthy, were found in class *b*, that is with a few widely scattered grains of starch. Hence this finding cannot be accepted as pathologic or significant. But they regard it as extremely significant that not less than 86 per cent. of the 59 patients with gastric ulcer showed macroscopic minimum retention, as also a certain proportion of the cases of gastric neuroses. They call attention especially to this, as the macroscopic minimum retention will enable us to discover a tendency to ulceration in dubious cases, and by keeping our eye on the sail, we can steer the course to safety instead of being surprised by a hematemesis in a supposed mere neurosis. The retention with gastric ulcer occurs intermittently, from pylorospasm. This explains the intermittent nature of the retention. Hypersecretion also favors retention of starch grains; the hydrochloric acid checks the digestion of starch by the saliva. With gastric cancer and achylia, this digestion proceeds unhampered, and practically no starch granules are found nine hours later. Niches and crevices in the stomach lining also favor this microscopic retention. Spasm of the pylorus may be induced by reflex action from gallstones or appendicitis, colitis or enteritis, but the percentage is only a fraction of that with gastric or duodenal ulcer. They emphasize in conclusion that the microscopic findings with cancer are of an entirely different mechanism and significance from those of macroscopic retention.

133 Influenza. V. Scheel.—p. 1766.
134 Etiology of Multiple Sclerosis. K. H. Krabbe.—p. 1772.

132. **Calcium Chlorid by the Vein in Intestinal Tuberculosis.**—Saxtorph was encouraged to try this treatment by D. Mandl's success with calcium salts in treatment of rebellious diarrhea with intestinal tuberculosis. Even in the severest cases the diarrhea is said to have been effectually arrested. Saxtorph's experience was equally favorable with it in three of the six cases in which he applied this treatment, namely, injection into a vein in the arm of a 5 per cent. solution of calcium chlorid. With this simple measure the patients were freed of all the symptoms of their intestinal tuberculosis for quite a long period. In the three other cases, no effect was apparent but there were advanced pulmonary lesions in all, and the system was evidently too deeply intoxicated and debilitated by a year of fever to respond to any treatment. At the same time, it might be well to give this treatment a trial even in these desperate cases, although naturally the results cannot be relied on as with the stronger patients.

PSYCHOSES ASSOCIATED WITH INFLUENZA

I. GENERAL DATA: STATISTICAL ANALYSIS *

KARL A. MENNINGER, M.S., M.D. (Topeka, Kan.)
Assistant Surgeon (Lieutenant, Junior Grade), U. S. N. R. F.; instructor in Neuropathology, Medical School of Harvard University
BOSTON

Sir William Osler[1] succinctly remarks that apparently "almost every form of disease of the nervous system may follow influenza." This postulate is seemingly quite justified by the accretion of neurophychiatric data from cases in the recent pandemic. The frequency of mental disturbances accompanying the acute illness in the epidemic has been the subject of frequent comment, and the wave of psychiatric material that followed in its wake was unexpectedly large and correspondingly interesting.

The literature on the mental diseases associated with influenza is remarkable for its paucity and the inadequacy of the communications, and this well applies to toxic psychoses in general. Bonhoeffer,[2] considered authoritative on the subject, ascribed this in a measure to the fact that "for the most part communications concerning the psychoses accompanying or following infectious disease proceed from the pens of others than psychiatrists. . . . A practical knowledge of the frequency and nature of the (mental) diseases encountered can only be learned from material that includes both internal and mental diseases."

Precisely because of the latter point, the Psychopathic Hospital affords unusual and highly desirable opportunities for the study and evaluation of data concerning the influenzal psychoses. Not only are many cases sent to the Psychopathic Hospital seen early in the course of the mental disease, but in all instances careful collateral study is made from the physical, serologic and social standpoints. The average influenza patient cared for at home is not seen by a psychiatrist; the average institutional patient is usually seen late in the course of the mental disease, long after aid from the physical side is practicable.

For these reasons the series of cases observed at the Boston Psychopathic Hospital during the recent epidemic are of particular importance. This institution serves a varied function in the community, but primarily it is a clearing house for cases of mental disease, and above all for the study of incipient (or borderline) mental cases. All of the cases here presented were regularly admitted patients, affording a certain definite uniformity of methods of study of the clinical material.

DIAGNOSTIC METHODS

A word is in place as to the methods used in the diagnosis of the "influenza" and of the "psychosis." As to the former, the statement of the attending physician, substantiated by the descriptions offered by the family or friends, was in most cases the chief evidence. In a considerable number we were able to make or confirm the diagnosis intramurally. In a few instances we have only the patient's word. For the accuracy of these we have no criterion or proof. On the other hand, the ubiquity of the disease, the singularity of its symptoms and course, and the absence of intercurrent epidemics in Boston at that time make the diagnosis of an acute febrile illness of short duration with respiratory tract symptoms and disproportionate prostration comparatively simple. Finally, it is certain that the percentage of error in the diagnosis is under the circumstances probably less than the average error in diagnosis of acute illness of all kinds, at all times, by all physicians.[3]

The psychiatric diagnoses in the Psychopathic Hospital are arrived at after this fashion. On the fifth day of the patient's stay, the case is presented to the entire staff by one of its members with the complete data of outside history, mental, physical and serologic examinations, and the special examinations, such as spinal fluid, roentgenographic, clinical chemistry, ophthalmoscopic and psychometric. At this time a preliminary diagnosis is made by vote. In a few cases this diagnosis is changed by or after the tenth day when the reconsideration of doubtful cases is made, usually at staff conference.

I hold no brief for the diagnostic ability of the staff of this hospital. I am glad to be able to refer to the statistical investigations of Lowrey,[4] the well substantiated conclusion of which is that the diagnoses made here are in some 85 per cent. correct (as measured by longer observation in other institutions).

STATISTICAL DATA

The epidemic appeared in Boston about September 15. From that time until December 15, a period of three months, 100 cases of mental disturbance associated with influenza were admitted here. Of these 100, data are complete on only eighty, and except for some general statistics it is the latter number which is considered.

Diagnostic Groups.—For the sake of statistical convenience and clarity it is desirable to introduce here a diagnostic grouping which will be elaborated on later in the paper. The psychiatric diagnoses in this series of cases vary, of course, within wide limits, including nine of Southard's eleven major groups of mental disease.[5] On the basis of numerical preponderance, however, they are readily classifiable into four groups:

Group I comprises those cases generally agreed to be states of delirium, dependent on the acute infection. "Infection-toxin delirium" seems to me better than the recognized reversal of the phrase, namely, "toxic-infectious," since from the name the latter may legitimately be interpreted to include incidents of delirium tremens superimposed on pneumonia.

Group II comprises the cases of frank dementia praecox.

Group III comprises the other forms of psychoses encountered which were thought to fit more or less precisely the generally recognized entities.

Group IV comprises the cases in which there was enough doubt or difference in opinion on the part of the staff to justify leaving the case unclassified. That is to say, *this is a group in which we did not feel certain of any one diagnosis.*

On the basis of this grouping, the numerical incidence of the cases was as shown in Table 1 and Chart 1.

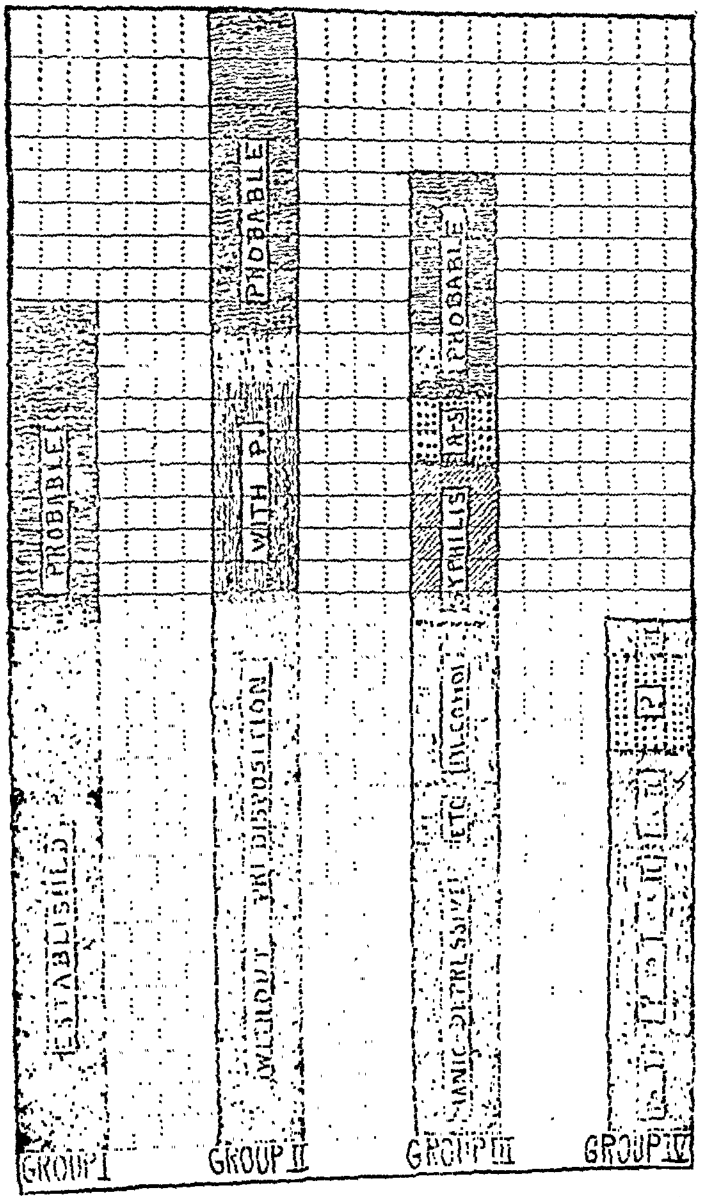

Chart 1.—A numerical summary of diagnostic groups. Vertical units represent individual cases.

The large size of Group IV will be remarked. It is here appropriate to point out that in many of these cases time will be the great diagnostician. Already one of the patients included in that group has returned to the hospital with this time a clear picture of dementia praecox. A forecast of probabilities, to be accepted only at its face value, is chiefly interesting in its confirmation of the results in the established groups. In other words, the indications from the unclassified group would seem only to augment in numbers the tendencies pointed to by the data of Groups I, II and III. Thus of that group, at the present time, three cases seem most likely to have been forms of delirium and three of dementia praecox; six cases are between those two diagnoses, and the remaining four cases are of other types. On a basis of probabilities, the totals of the eighty cases, plus the probabilities in the remaining twenty cases of the hundred, are presented in Table 2 and in Chart 1.

TABLE 1.—NUMERICAL SUMMARY OF EIGHTY CASES

Group I, delirium	16
Group II, dementia praecox	25
Group III, other psychoses	23
Group IV, unclassified	16

TABLE 2.—NUMERICAL SUMMARY OF ONE HUNDRED CASES ON BASIS OF PROBABILITIES

Group I, delirium	26
Group II, dementia praecox	35
Group III, other psychoses	30
Group IV, unclassified	9

From Tables 1 and 2 there appears at once the most conspicuous and remarkable fact of the present data. This is the unexpected frequency of dementia praecox as a postinfluenzal psychosis. It occurred more frequently in this hospital than all other psychotic forms combined, delirium excluded, and even more frequently than the delirium which should be the most common. In the latter cases, however, the fallacy is quite obvious, since the great majority of deliria are never sent to a hospital for mental diseases. In fact, it may be parenthetically remarked that some authors do not recognize delirious states as psychoses, the chief reason being, however, that there is no established definition of psychosis, rather than that the nature of delirium is not appreciated. However, the strength of the first comparison is undiminished, and becomes more remarkable on further consideration. This is, of course, necessary, since not all of the cases of dementia praecox were storms from a clear sky. The matter will be considered in detail below.

Sex.—The 100 cases comprise forty-three males and fifty-seven females. The eighty cases more extensively studied comprise thirty-four males and forty-six females. In both groups the proportions are the same, the females preponderating by 57 per cent. to 43 per cent.

TABLE 3.—SEXUAL DISTRIBUTION ACCORDING TO PSYCHIATRIC DIAGNOSES

	Eighty Cases, Established Diagnoses		One Hundred Cases, Probable Diagnoses	
	Males	Females	Males	Females
Group I, delirium	9	7	14	12
Group II, dementia praecox	4	21	8	27
Group III, other psychoses	15	8	16	14
Group IV, unclassified	6	10	5	4

On the basis of the tentative groupings detailed above, the sexual distribution appears as in Table 3. The chief deduction from this table is the predominance of the female sex in the patients presenting the picture of dementia praecox. Relative equality obtains elsewhere despite the influence of alcohol in augmenting the proportion of males in Group III (e. g., acute alcoholic psychoses).

---

[5] Southard, E. E.: J. Lab. & Clin. Med. 4:31 (Nov.) 1918; Tr. Am. Neurol. Assn., 1918.

Age.—The age range was from 16 to 69, the youngest patient being a male, the oldest a female. The youngest woman was 18, the oldest man 61. The average of all was 31.7 years, without marked differences in the sexes (e. g., for Group I, males, thirty-three; females, thirty-one).

The average ages of patients in the diagnostic groups appear in Table 4. There is a statistical suggestion from this table of the bizarre hypothesis that the age is a factor in the determination of the form of resultant psychosis. Thus below, say 18, no serious mental complication is common. In the succeeding decade the tendency is toward the development of dementia praecox; in the next decade, toward some other psychotic entity. It is not pretended that this theory is to be taken entire, but neither is it wholly to be ignored. Nothing that contributes to the further elucidation of the question, "Why does a specific individual develop dementia praecox?" should fail to receive consideration.

Time Factors.—The two principal considerations concerning temporal factors are the duration of the influenza, particularly in relation to the psychoses engendered, and the chronology of the influenza and respective psychoses.

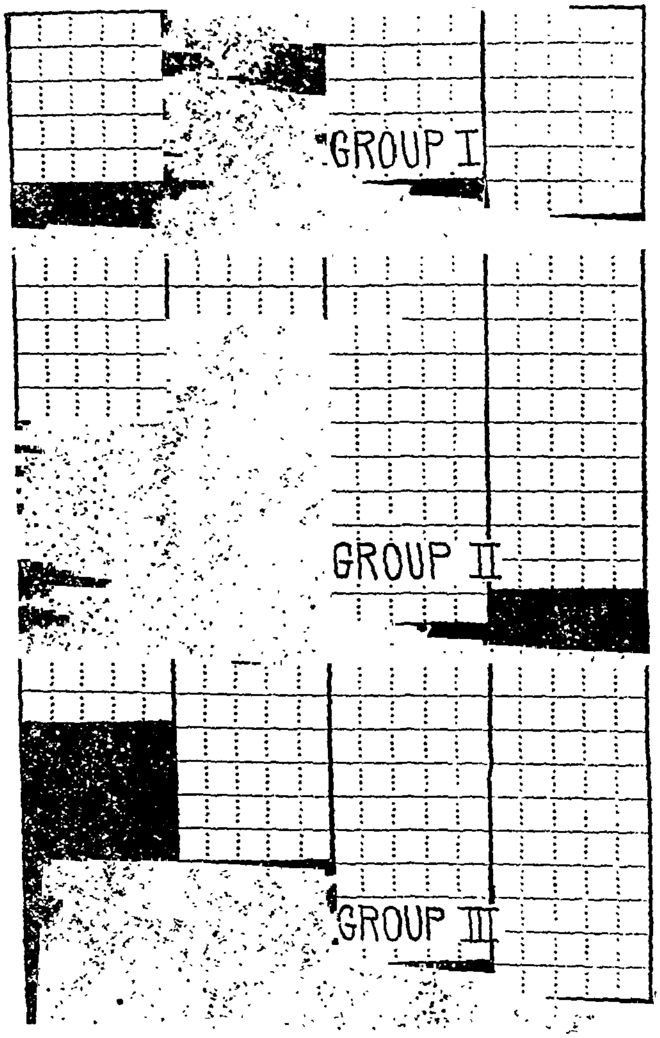

Chart 2.—Influence of duration of influenza on number of resultant psychoses. Vertical units represent individual cases, horizontal units, days.

Taking up first the matter of the duration of the influenza, we at once encounter a large factor of unreliability. In the first place, there might be some theoretical objections to the designation of any particular moment as the terminal moment of a specific attack of influenza. This can be pragmatically circumvented by assuming that the influenza terminates when the fever abates, that is, when the *temperature* returns to normal and there remains. Not only, however, are many of the patients not informed by their physicians of the precise date of this termination, but *in not a few* cases the physicians themselves evidently did or do not know. However, the difficulty was actually more apparent than real, because in most cases in which it was not known it could be estimated from the relative time spent in bed, the subjective symptoms, etc.

TABLE 4.—AVERAGE AGE OF PATIENTS ACCORDING TO DIAGNOSTIC GROUPS

I, delirium	32
II, dementia praecox	23
III, other psychoses	40
IV, unclassified	34

TABLE 5.—DURATION OF ATTACKS OF INFLUENZA, FROM HISTORIES

Uncomplicated Influenza:	
Range of duration	From 2 to 17 days
Average duration (49 cases averaged)	6 days
Influenza with Known Pneumonia:	
Range of duration	From 3 to 25 days
Average duration (19 cases averaged)	13 days

On this working basis the facts presented in Table 5 were obtainable. The reputed duration of the acute illness was, as may be observed, quite variable; but the listed cases fall into four rather clearly defined groups: those of a duration of less than five days, those of from five days to a week in duration, those lasting from eight days to two weeks, and those exceeding that length of time. Thirty-six per cent. of all the cases fall into the second group. On this basis, Table 6 is presented to show the relative frequency of each, and of the development of dementia praecox as the specific psychosis. The same is represented graphically in Chart 2, in five day periods.

The conclusions justifiable from these statistics are, first, that the duration of the influenza or influenza and pneumonia precipitating mental diseases is probably not appreciably greater than that of the average attacks of influenza or influenza and pneumonia in the present epidemic. The frequency of pneumonia (about 25 per cent.) is certainly larger than that obtaining generally, but this may in part be due to the fact that at least two thirds of our "pneumonia" patients were brought here, more or less moribund, because of the deliria of profound toxemia.

The second conclusion concerns the tendency of dementia praecox to show no constant relation to the duration of the influenzal attack precipitating it. As large a percentage of cases of dementia praecox followed the briefer attacks as followed the most prolonged and presumably more severe.

TABLE 6.—INCIDENCE OF PSYCHOSES AND PARTICULARLY OF DEMENTIA PRAECOX ACCORDING TO DURATION OF INFLUENZA

Duration of Influenza	Number of Cases, All Forms	Cases of Dementia Praecox	
		No.	Per Cent.
From 1 to 4 days	18	6	33
From 5 to 7 days	29	10	32
From 8 to 14 days	18	5	28
From 15 to 25 days	12	4	33

In the matter of the chronological relationships between the influenza and the psychoses, graphic presentation is most helpful.

Chart 3 presents the average interval between the somatic and psychic episodes. To be more precise, it represents the relative chronology of the fever accompanying influenza and the manifestation of psychotic symptoms following it. As will be noted in all instances save the deliria, the psychosis began on the average after the fever had abated. This interval varies from less than two days in the alcoholic psychoses to 8.5 days in the cyclothymic psychoses.

This chart is a partial verification of Bonhoeffer's principle, that "in general one may say that the later in the convalescence the psychosis begins, the more doubtful is its symptomatic character and the more frequently does it bear the stamp of endogenous psychic disturbances." It is also a valuable witness to Bonhoeffer's theory of the elaboration of the endotoxins as a result of stimulation by acute infection toxins, the former bringing about the psychoses.

An analysis of this interval by five day periods is presented in Chart 4. This chart has reference to the day of onset of the psychosis, as compared to the days of the influenza; that is, *those cases of psychosis manifested during the first five days of the illness make up the first pillar, those during the second five days the second pillar, etc.*

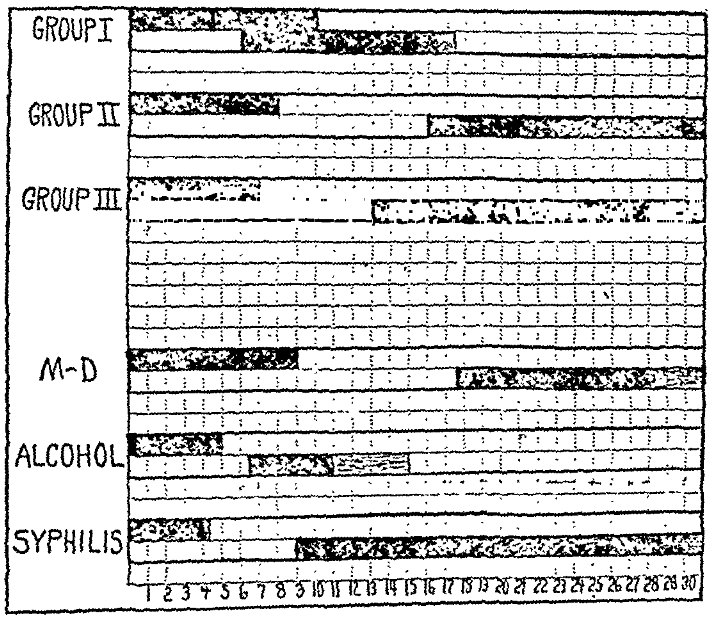

Chart 3.—Relative chronology of fever and psychosis. In each couplet the upper bar represents the influenzal pyrexia in days duration, the lower the psychotic manifestations. Units represent single days.

The conspicuous evidence offered by this chart is the tendency of simple delirium to occur early in the course of the disease, the postinfectious or "collapse" delirium being quite exceptional; and, on the other hand, the uniform rate of incidence of dementia praecox throughout the postinfluenzal period. Thus no cases of delirium occurred after the fifteenth day, whereas there were as many cases of dementia praecox between the twentieth and twenty-fifth days as between the first and fifth, or any other period. Further time studies have been made of the dementia praecox cases, but these must be omitted here for want of space.

SYMPTOMATOLOGY

A representative but synthesized case history reads as follows:

During the convalescence from influenza, Miss X suddenly became excited and rushed from her bed into the street, screaming. She was recaptured and confined in bed, but seemed to be bewildered, deluded and hallucinated. The motor excitement faded: the perverted ideation became augmented, and the family physician advised the Psychopathic Hospital. At about this stage the diagnosis is always in more or less doubt between various obvious possibilities. Subsequently the symptoms follow in most cases a more or less stereotyped course and the diagnosis becomes clear; that is, one case will progressively clear up and the patient be sent home recovered, with a diagnosis of postinfluenzal delirium; another will manifest more and more evidences of schizophrenia and be committed with a diagnosis of dementia praecox, etc.

Depression is traditionally the postinfluenzal symptom *par excellence*. Osler comments on it; most writers in psychiatry as well as general medicine follow suit. But depression as an emotional state of the psychoses following influenza is not strictly comparable with the depression which presumably is common after the disease in nonpsychotic subjects. (I am aware of one instance in which a mild tendency toward hypomania rather than the reverse was observed in a normal young man, and so recognized by himself.) Aside from a few cases of postinfluenzal depression in which the diagnosis was in doubt between the normal and the psychotic, depression was in this series distinctly uncommon. Only three cases of the depressed phase of manic-depressive psychosis were encountered. Only about a fourth of all the cases showed any depression at any time, and it was rarely constant when present.

The heterogeny of symptoms is manifest from the divers forms of psychoses presented. Certainly the most common two are *delusions and hallucinations.* The delusions are of all sorts: somatic, referred, paranoid, transformation, grandeur, etc. One sort or another were present in seventy of eighty cases. Hallucinations in one or more fields occurred in all of the cases diagnosed dementia praecox, and in all of the cases of delirium, and in two thirds of the remaining cases. The constancy of hallucinations in delirium as here seen might arouse curiosity as to why Regis and others have specified a particular "hallucinatory" type of delirium (confusion mentale aiguë), as if hallucinations were not generally present.

No cases were monosymptomatic. In the first two groups, however, there were characteristic symptoms. In the deliria, it is amnesia. This was present in all cases, either as an amnesia during the acute psychotic period for past events (including the paramnesia of the Korsakow syndrome) or an amnesia after the acute psychosis for events transpiring during it, or, as not infrequently occurred, both. The second form is an integral symptom of delirium, but it is not an absolute differential point, as it occasionally occurs in dementia praecox and some other forms.

In the dementia praecox cases the characteristic and omnipresent symptom was schizophrenia, used in the symptomatic sense. As this is, in fact, the criterion of the diagnosis of dementia praecox, the foregoing statement is axiomatic. A more remarkable fact is the occurrence of distinctly schizophrenic symptoms in cases in which the patients quickly recover and which are necessarily diagnosticated delirium. Six cases were left in doubt because of this fact, and one third of the cases diagnosed delirium showed at one time or another frankly schizophrenic symptoms.

Group III is too heterogeneous to allow of any such representation. The specific psychoses were so far as diagnosticated more or less true in type, and this is not the place to review the symptoms of the recognized psychoses.

Motor excitement and emotional acceleration were not conspicuous except in Group III. Here both the alcoholic psychoses and the cyclothymoses (especially manias) showed the characteristic hyperkinesis and hyperthymia.

DIAGNOSTIC GROUPS

The four groups used throughout this paper are, of course, by no means as homogeneous as their captions might suggest, and it is proposed to analyze, in a degree, their componency. The lack of space prohibits illustration by means of case histories or even abstracts, but as these are to appear later, it is perhaps desirable to present here only the structural framework of the series.

Group I.—The cases diagnosed "toxic-infectious delirium" or "delirium with infectious disease" (American Medico-Psychological Association nomenclature) embrace three forms of delirium. These forms are not based, as by Kraepelin,[6] on ambiguities, such as "confusion" and "exhaustion," or as by Bonhoeffer,[2] on the predominant symptom. They are based on the most simple and the only uniform factor, namely, time. It is in our experience here quite impossible to follow either Kraepelin or Bonhoeffer in distinguishing types of delirium. On the other hand, the deliria are in all cases of one of three types: prefebrile delirium; (cum-) febrile delirium, or postfebrile delirium. Either of the first two may be prolonged over into the subsequent period. This classification is so preeminently valuable from a pragmatic standpoint, and the subdivisions of the German writers so bewildering and so conducive to ambiguous descriptions, that for the present I feel that no further justification is required.

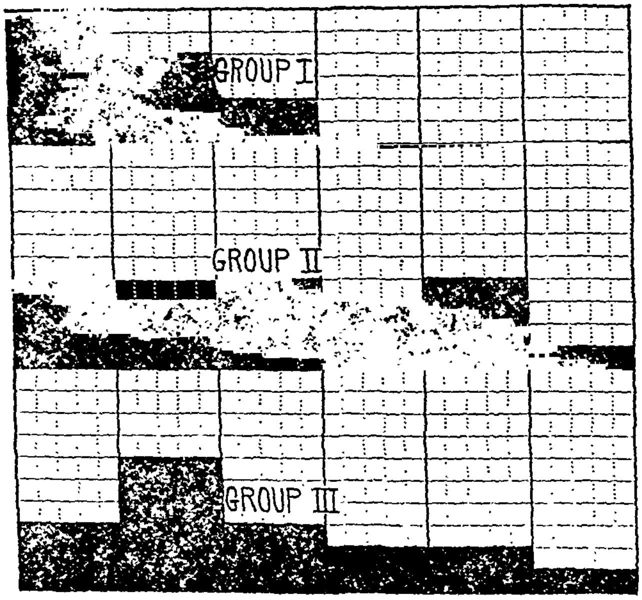

Chart 4.—Influence of duration of influenza on time of onset of resultant psychoses. Abscissas represent time periods in five day groups; ordinates, number of cases.

Statistically, there were in the present series one, possibly two, cases of prodromal delirium type.

Of the typical delirium concomitant with fever, the present series includes twelve. Of these patients, seven died. In one instance the fever abated two weeks before death.

Of the postfebrile deliria there were three, one of which was fatal. In one of the other two the delirium lasted two weeks.

Any general hospital could probably furnish more examples of all of these types than a psychopathic hospital. These cases are in a sense representative of the more severe forms of delirium.

Neurologic signs were not infrequently present. I am elsewhere reporting with Myerson an instance of severe bilateral optic neuritis which occurred in but one case, although all eye grounds were examined as a routine. One woman, aged 40, with typical delirium, presented absent pupillary and patellar reflexes, with muscular fibrillation. Several cases were noted with transient Argyll Robertson pupils. Convulsions were rare, occurring in only one case, and incidently in one fatal case in one of our nurses, not included in this series.

The spinal fluids were examined in most cases, and in only one instance was there any inexplicable change. This was a case of postfebrile delirium, with slight increase of albumin and globulin, and a mild midzone gold reading; Wassermann tests were negative. These negative findings do not coincide with the postmortem findings on spinal and cerebral fluids of patients dying of influenza, in which Southard and Canavan have found marked changes. (See note on Meningeal Reactions in Influenza, in preparation.)

Group II.—The patients who developed dementia praecox during or soon after an attack of influenza may de differentiated into three important groups. These are: (1) those with preexistent indications; (2) those with morbid family history, without previous tendency, and (3) those with neither. Of the first class there were, of course, two varieties: those with previous attacks of acute psychosis, dementia praecox episodes, and those who, without previous episodes, manifested a tendency to the seclusive, egocentricity, etc. In both of these types the acute psychotic episode seems to have been precipitated by the influenza, a process frequently mentioned in the literature, but by no means understood.

The patients in whose family history there appear pathologic elements — a psychotic father, a feebleminded brother, etc. — are separately grouped because of the possible contribution of these elements.

The group in which there was no previous indication, no evinced tendency and no morbid family history is certainly the most momentous group of this series. It is subdivided into those complicated by parturition, and those due solely to the influenza. In this group the influenza (and parturition) seemed to act by directly inducing a process for which there were no previous indications. There are as yet insufficient data to conclude that the infectious process may be the direct etiologic factor (perhaps via some such mechanism as Bonhoeffer proposes) of dementia praecox. Nevertheless the evidence which these cases constitute for the organic view of dementia praecox, as held by Alzheimer, Dide, Deny, Southard, Regis, Rosanoff and others, is of considerable weight. What effect it will have on the view of "curable dementia praecox," of which only rumors have thus far reached us *ex bello*, no one can say.

---

[6] Kraepelin, E.: Psychiatrie, Ed. 8.

The numerical frequency of the foregoing subdivisions of Group II appears in Table 7.

Group III.—This heterogeneous group includes cases of the usual psychoses which were precipitated in acute form by the influenza. This does not relate to their permanence, since forms of manic-depressive psychosis will likely all prove transient; of neurosyphilis, presumably permanent. All began during the defervescence of, or convalescence from, the influenza. The cases of neurosyphilis are included, as the others, because although it is indisputable that the neurosyphilitic process precedes the influenza, the symptoms were so exaggerated or the process so accelerated that for the first time the conduct of these patients became such that institutional care was considered necessary.

TABLE 7.—SUBDIVISIONS OF THE DEMENTIA PRAECOX GROUPS

With preexistent indications		9
Definite episodes	3	
Disposition only (including 1 parturient)	6	
With morbid family history rient)		4
With neither personal nor		13
Influenza plus parturition	2	
Influenza (or pneumonia) alone	11	

An outline with the numerical frequency of each group appears in Table 8.

Group IV.—This group of cases of dubious diagnosis consists of sixteen cases. Of these, three were most likely postfebrile deliria; six were indistinguishable between postfebrile delirium and episodic dementia praecox; three, in my opinion, will likely prove to be dementia praecox, and five remain undiagnosticated because of unusual combinations of symptoms, insufficient data, etc.

The striking point in this group is the frequency of difficulty in distinguishing between postfebrile delirium and dementia praecox. There is not time here to dilate on this theme, or to recall the references to this difficulty made by the French authors who regard dementia praecox as essentially a toxic psychosis. It is sufficient to indicate that this fact, and the presence of schizophrenic symptoms in one third of the cases diagnosticated delirium, add considerable force to the suggestion made above from the statistics in Group II, concerning infectious processes as the possible etiology in some cases of dementia praecox.

TABLE 8.—STATISTICAL ANALYSIS OF GROUP III

So-called "functional psychoses"		11

Alcoholic psychoses	5	
Neurosyphilitic psychoses	5	
General paresis	4	
Diffuse form	1	
Arteriosclerotic psychoses	2	

Another classification of the diagnostic groups is suggested by the facts presented. The influenza acts in two ways: as an inciting factor for a process not previously manifest, and as an exciting factor for rendering visible a previously latent or semilatent process. Thus the cases of manic-depressive psychosis with first attack following influenza illustrate well the first tenet, and the augmentation of neurosyphilitic processes the second. Our knowledge concerning both methods is at present in a clouded state, and only much careful study of series of cases such as the present will elucidate the matter.

From such a point of view the cases of this series may be presented numerically as in Table 9.

TABLE 9.—NUMERICAL SUMMARY ACCORDING TO WAY INFLUENZA ACTED

Latent Processes Activated:		
Dementia praecox	8	Total 32
Manic-depressive psychosis	6

Dementia praecox	17	
Manic-depressive psychosis	3	
Other psychoses	0	
Unclassified	12	

COURSE

The course of the psychoses has in general been indicated in connection with the individual groups. The delirious patients either recover mentally and physically or die. Those diagnosticated as having dementia praecox are all alive at the present time except two, who died within the month. There have been no deaths in Groups III and IV. Necropsy results will appear later.

Statistically the present status and probable prognosis is represented in Table 10.

TABLE 10.—COURSE OF THE PSYCHOSES

Groups	I	II	III	IV
Transient	10	0	14	6
Interrupted by death	6	2	2	3
Permanent	0	23	7	7

SUMMARY AND CONCLUSIONS

1. One hundred cases of mental disease associated with influenza in the recent pandemic have been studied at the Boston Psychopathic Hospital. Eighty of these have been intensively analyzed.

2. The variety of mental disturbance manifested is wide, embracing in this series nine of Southard's eleven groups of mental disease. For convenience they are readily classifiable into four groups: delirium, dementia praecox, other psychoses and unclassified. Of these the second (dementia praecox) is the largest group numerically.

3. That age may be a factor in determining the form of psychosis evolved is suggested by an analysis of the average ages of the groups.

4. Analysis of the time relations proves that the duration of the influenzal attacks in the patients developing psychoses is not appreciably greater than the average as reported in the present epidemic, nor does the duration modify the form of psychosis developed.

5. There is in most instances an interval between the termination of the influenza and the first manifestation of symptoms of psychosis, the averages varying from two to eight days in all save the febrile deliria. Herein, Bonhoeffer's principle of the relation of interval and complexity of the psychoses is supported.

6. The symptomatology is as complex as the nosology. Delusions and hallucinations are the most common symptoms, and depression is relatively infrequent contrary to the case in mentally normal subjects.

7. The states of delirium encountered are best classified as of three forms, on a temporal basis: prefebrile delirium (prodromes), (cum-) febrile delirium, and postfebrile delirium (collapse delirium,

exhaustion delirium, confusion, etc.). This accounts for all cases and avoids ambiguity.

8. Neurologic signs were few; ophthalmoscopic examination negative, save for one instance of bilateral neuritis, and spinal fluid examination negative save for one instance of modified colloidal gold reaction.

9. An organic basis for some instances of the picture denoted dementia praecox is supported by the preeminent frequency of its occurrence in this series (31 per cent), the age factor above mentioned, the frequency of schizophrenic symptoms in otherwise typical cases of delirium, and the occurrence of several (six or more) cases in which a diagnosis could not be made between delirium and dementia praecox, despite the presence of all diagnostic aids.

10. The psychiatric prognosis in influenza justifiable on the basis of the present series may be expressed in general as delirium (with recovery), death or dementia praecox. This excludes cases of previous psychotic basis, such as alcohol and neurosyphilis.

ATROPIN AND INDUCED ANTIANAPHYLAXIS

AS A PROTECTION AGAINST ACUTE ARSPHENAMIN REACTIONS [*]

J. H. STOKES, M.D.
ROCHESTER, MINN.

The acute nitritoid or anaphylactic reaction to the intravenous injection of arsphenamin has become rather familiar to the profession through the peculiarities of certain brands of the drug that have of late years been placed on the market. In the management of a few cases, or in the treatment of young, robust persons, the average acute reaction may be an annoyance rather than a critical complication. None the less, it has resulted fatally, and in the enfeebled or in those with grave constitutional ailments it may give rise to alarming situations. There is also a type of patient who needs the drug, but who, instead of an occasional reaction, exhibits a persistent marked idiosyncrasy which subjects him to repeated anaphylactic storms with successive injections that may force an abandonment of this form of medication.

Heretofore, the means for the control of acute reactions due to the administration of arsphenamin have been confined to special care in the preparation of the patient (catharsis and empty stomach), caution in the alkalinization of arsphenamin solutions, and to the use of the epinephrin solution suggested by Milian[1] in from 5 to 10 minim doses as a means of controlling the reaction after it develops. Epinephrin may also be used as a prophylactic, as noted, for instance, by Berman.[2] This drug, however, administers a shock of no mean intensity by its powerful effect on the vascular system, so that I have seen occasions in which patients have for the moment seemed in as much risk of serious damage from the therapy as from the original arsphenamin reaction. The frequency of nitritoid crises during the period in which German-made arsphenamin and neo-arsphenamin were being supplied to this country by submarine furnished an incentive to the development of a less vigorous prophylaxis for the reaction, which could be relied on to make repeated injections possible even in the face of a marked idiosyncrasy on the part of the patient. It occurred to me that such a prophylaxis might be based on the clinical resemblance of the nitritoid crisis and the reaction produced by imperfectly alkalinized arsphenamin solution to anaphylactic shock. A physiologic means of combating anaphylactic shock, it seemed to me, might protect against acute nitritoid crisis, and at the same time have theoretical interest as an indirect demonstration of the true anaphylactic nature of the phenomenon. This seemed the more worth while because of the theory, recently advanced by Schamberg, Kolmer and Raiziss,[3] that the reaction was due to the physiologic effect of an impurity (substance X) rather than to anaphylaxis per se.

Support for the belief that the nitritoid crisis is a form of anaphylactic shock rests on more than mere clinical analogies. Swift[4] early undertook to explain the reaction as a form of shock by showing that guinea-pigs could be passively sensitized to a mixture of guinea-pig serum and arsphenamin, and would on subsequent injection develop a true anaphylactic response. Since, however, the older conception of anaphylaxis required that a previous sensitizing dose of the allergy-producing agent be administered, the explanation of Swift seemingly failed to cover those cases in man in which nitritoid crisis developed on first injection.

The development of the newer physical conceptions of the mechanism of anaphylactic shock, made possible by the work of Bezredka and Strobel,[5] Kopaczewski and Mutermilch,[6] Jobling and Petersen,[7] Novy and De Kruif[8] and numerous other investigators, has done away with the objection to Swift's explanation. One of the essential facts in the production of anaphylactic shock may now be regarded as a change in the dispersion of the colloids of the blood serum. An investigation which has special application to the problem of arsphenamin reaction in its relation to anaphylaxis is that of Friedberger and Tsuneoka,[9] who found that the injection of a powder, such as kaolin, into the blood stream, gives rise to anaphylactic shock. MacKee,[10] among others, observed in 1912 that the intravenous injection of arsphenamin in acid solution produced a precipitate, and a reaction in the patient proportional to the concentration of the solution and the rate of injection, that is, the rate of formation of the precipitate in the blood stream.

The application of MacKee's observation, which has been repeatedly confirmed by subsequent observations on the toxicity of acid and partially alkalinized solutions of arsphenamin, to the problem of arsphenamin anaphylaxis, may be made by way of Friedberger and Tsuneoka's demonstration of the effect of fine precipitates in the blood stream. Thus interpreted, the reaction to acid and imperfectly alkalinized arsphenamin is anaphylactic shock due to the formation of a precipitate in the blood. Reasoning by analogy, the closely similar picture of nitritoid crisis may be anaphylactic shock produced by the formation of a precipitate in the blood.

The demonstration of the correctness of this reasoning has recently been accomplished by the work of Danysz.[11] and of Berman. Danysz has shown that the arsphenamin solution is essentially colloidal, and that on its injection, the arsphenamin base is precipitated out by the constituents of the blood plasma, and then formed again into soluble organic derivatives. The rate of this precipitation is dependent to some extent on the alkalinity of the solution, and on the peculiarities of the individual blood plasma. If the solution is imperfectly alkalinized or if the serum of the patient is abnormal, rapid precipitation followed by acute reaction ensues. This observation links together the reaction to acid solutions of arsphenamin and the nitritoid crisis. Berman has recently shown that even with a properly prepared solution, precipitation occurs in the serum of hypersensitive patients. He differs from Danysz, however, in believing that this precipitation involves the proteins of the serum rather than the arsphenamin base. He believes, further, that a tendency to nitritoid crisis can be predicted by testing the serum of a patient with a solution of arsphenamin before the injection is given.

The question as to whether the entire phenomenon of allergic reaction to arsphenamin may be explained either by insufficient alkalinization of the solution or by peculiarities in the patient's blood serum can certainly not be regarded as completely settled. There remains to be explained the large body of observation on variations in the toxicity of arsphenamin itself. The proposal of Schamberg and his collaborators that there is a factor in the preparation of arsphenamin, an impurity of as yet unknown constitution, present in the drug, is not at all incompatible with an allergic explanation of the reaction. It is conceivable that it is not the arsphenamin base alone which precipitates, but the serum proteins as well, and that this precipitation of the serum proteins may be accomplished with especial ease even in comparatively normal persons, by a substance present as an impurity in the drug. No other satisfactory explanation can be found, to my mind, for the extreme frequency of reaction to certain brands of the drug, and its extreme rarity under identical technical conditions, in others. On my own service, in which the operators and the technic of operation remain unchanged for months and even years at a time, there can be no other satisfactory explanation for the fact that during 5,000 injections in which German preparations were used there were considerable periods when scarcely a day passed without a nitritoid crisis, while in 7,000 subsequent injections in which arsenobenzol-Policlinic and novarsenobenzol-Billon have been employed, the nitritoid crisis has become so rare that we have been compelled to all but abandon the work necessary to confirm the results presented in this paper. We have, moreover, had the opportunity to observe the production of crisis by an accurately alkalinized but evidently impure preparation used on the assurance of the manufacturers, in every one of five successive patients known not to present any personal idiosyncrasy to the drug. There can be little doubt in the minds of large users of arsphenamin that there is a factor of toxicity and a tendency to the production of anaphylactic response in certain preparations which cannot be explained in absolutely general terms, and is probably due to specific impurities.

My own attempt to devise a protection against acute arsphenamin reaction, and incidentally to support the view that the phenomenon was a manifestation of anaphylactic shock, consisted (1) in an attempt to employ the well-known inhibitory effect of atropin, recently experimentally demonstrated, for example, by Pelz and Jackson[12] in the dog, and (2) in an effort to induce antianaphylaxis to the drug according to the methods of Bezredka and Steinhardt.[13] It should be noted that Swift had suggested the possibility of antianaphylaxis on the basis of a casual observation that if a nitritoid crisis set in, and the injection was stopped, it could sometimes be resumed again in ten minutes without further ill effect. Work of this kind in patients can be undertaken with an expectation of trustworthy results only when the idiosyncrasy for arsphenamin is so definite and persistent that it is possible to exclude the factors of imperfect alkalinization, variations in the chemical composition of the drug as marketed, variations in the patients' individual state of health, and neurotic and hysterical factors. The number of patients meeting such control requirements is necessarily small, so that in a series of 12,000 injections it has been possible to employ the procedures described, with confidence in the results, in only about a dozen cases. The first case in which the method was employed is typical of the response in the entire series, and is here summarized. It should be noted that in this case neo-arsphenamin was used, thus eliminating the question of proper alkalinization of the solution, so important in judging of a reaction to arsphenamin.

REPORT OF CASE

The patient was a rather stolid Swedish girl who took her idiosyncrasy in a very matter-of-fact manner. She was under treatment for a florid follicular secondary syphilid. Following her initial intravenous injection of neo-arsphenamin she exhibited a rather sharp Jarisch-Herxheimer reaction in spite of a moderate dose. The second injection at the end of a week was without reaction. After the third she developed a marked, unexplained rise of temperature. The interval between the third and fourth injections was then lengthened to two weeks, and the fourth injection passed without event. Following the fifth injection she again developed a marked rise of temperature and vomited. No further injections were given for six weeks. During her first course, then, this patient had shown gradually increasing evidence of intolerance of neo-arsphenamin.

The first injection of the second course marked the beginning of her nitritoid crises. Two minutes after the injection of 0.3 gm. of neo-arsphenamin in concentrated solution by the method of Ravaut, she developed on the table the characteristic intense scarlet flush with edema of the face and neck, cough, stridor, asthmatic breathing, prostration and vomiting. She recovered rapidly following a subcutaneous injection of 10 minims of a 1:1,000 solution of epinephrin.

On the next injection, one week later, the first attempt to protect the patient with atropin was made, a dose of 1/50 grain being given hypodermically fifteen minutes before the injection of neo-arsphenamin. The dose of neo-arsphenamin was 0.6 gm., double that of the preceding injection, and was given by the same technic. Only a very slight reaction occurred. There was no flush or pulmonary disturbance. The patient vomited once on returning to her room.

On the third injection, one week after the second, the dose of neo-arsphenamin was increased to 0.7 gm., the dosage of atropin and the time interval being identical with that on the preceding occasion. This time the reaction was all but negligible, although the patient tasted and smelled the drug and was distinctly nauseated.

The fourth injection was given one week after the third, the dose of neo-arsphenamin again being 0.7 gm. On this occasion, through a misunderstanding, the patient received only 1/150 grain of atropin subcutaneously. That this dose was insufficient was promptly demonstrated by the occurrence of a crisis on the table, with marked flushing, edema and vomiting.

Just preceding the fifth injection, also through a misunderstanding on the part of an assistant as to the size of the dose of atropin, the patient received 1/75 grain of atropin subcutaneously. The injection of neo-arsphenamin, 0.6 gm., which followed, caused a mild reaction, with flushing and vomiting.

So strongly did the efficiency of atropin in proper dosage suggest the anaphylactic nature of the reaction, that it was decided to attempt the production of anti-anaphylaxis in this case. Accordingly, one hour before the administration of the next injection of neo-arsphenamin, the patient was given 0.05 gm. of the drug in 0.5 c.c. of water, intravenously. The neo-arsphenamin used was of the same control number as that employed for the previous injection, which had shown itself capable of producing marked reaction in this patient (Control V U J). Following the injection of the half decigram dose, the patient became slightly dizzy and was a trifle nauseated on returning to bed. One hour after the preliminary injection the patient received 0.55 gm. of neo-arsphenamin intravenously in concentrated solution, injected at the usual rate. The complete inhibition of all reaction was striking. There was no flush, no nausea nor vomiting, no dizziness, cough nor stridor. The eyes became slightly suffused. The patient felt so much better than usual as to astonish her and all those who knew of her reactions. She was returned to her room, and no reaction was reported for twenty-four hours. At the end of this time, without rise of temperature or any other marked systemic symptoms, a generalized macular erythema of the typical late toxic type appeared. It was not accompanied by constitutional symptoms and disappeared two or three days later. It was judged wise, however, not to invite an exfoliative dermatitis by any further arsenotherapy.

COMMENT

This case was surrounded by all the precautions against pseudoreaction that we could devise. The reactions observed were typical of the acute nitritoid crisis and we felt that the sequence of events, as described, had not been modified by presuppositions on the part of the patient or by hysterical manifestations. Abundant objective evidence of the patient's intolerance was available. Not the least interesting suggestion based on these observation is the possibility that the acute anaphylaxis and the delayed toxic erythema are different types of reaction. An antianaphylaxis which was developed to protect the patient against the former failed to protect against the latter complication. The influence of atropin seemed to be quite definitely a function of the dosage, and doses below 1/50 grain failed to protect the patient against shock. It is to be regretted that circumstances made it impossible to transfer the problem from the patient to experimental animals for a more thorough study.

Since its successful employment in the case described, we have resorted a number of times to the induction of antianaphylaxis as a protection against acute arsphenamin reaction, notably in the treatment of patients with tuberculids, who show an idiosyncrasy in about 50 per cent. of the cases. I have noted with interest Danysz' impression, which my experience confirms, that small preliminary injections "vaccinate" the susceptible patient, so to speak, against the larger doses, an observation which Danysz supports by animal experiment, and offers likewise as a rationale for the regulation of dosage in treatment, and a means for increasing individual tolerance of the drug.

SUMMARY

1. The acute "nitritoid" crisis or reaction to arsphenamin is a form of anaphylactic shock, explainable on physicochemical grounds as the result of a precipitation either of the drug from its colloidal solution, or of the colloids of the blood plasma, by the drug, or by an impurity. The reaction following the injection of an acid or only partially alkalinized solution of arsphenamin either too rapidly or in too high concentration is presumably of the same type.

2. The nitritoid crisis can apparently be inhibited by a previous injection of atropin (1/50 grain), which further suggests that the reaction is a form of anaphylactic shock.

3. The induction of antianaphylaxis as described above further supports the belief that the nitritoid crisis is a form of anaphylactic shock.

4. The induction of antianaphylaxis in patients exhibiting persistent idiosyncrasy to arsphenamin or neo-arsphenamin has proved clinically useful, and, as a means of increasing their tolerance of the drug, deserves further trial and study.

Universal Compulsory Insurance Against Tuberculosis.—Dr. P. J. Ménard outlines in the *Presse médicale,* Nov. 25, 1918, a plan for universal compulsory insurance against tuberculosis, the funds from which would serve for the fight against tuberculosis. His scheme is something like the German compulsory social insurance against sickness, but the tax or insurance dues imposed would include all classes of society, not merely the wage earners. He protests that the fight against tuberculosis should not be left to charity or private initiative, but should be as much a matter of course as the tax on land, and the person contracting tuberculosis, whatever his social standing, should be compelled to do everything necessary to aid in throwing it off, with all the financial aid needed for this, and without his feeling that charity is being doled out to him. The fight against tuberculosis, Ménard reiterates, is first and foremost a question of money. It requires a permanent organization with a stable and automatic income, such as a per capita tax would supply. The money thus provided could be loaned to towns and provinces wishing to erect preventoriums, sanatoriums, hospitals, etc., for the tuberculous. Germany, he states, had nearly a third of the capital of its sickness insurance societies thus loaned out, a total of 365,920,290 marks, about $91,230,000. There are thirty-one regional and nine occupational sickness insurance societies, and they collect the dues under state supervision. The wage earners and the employers pay an equal sum weekly, totaling from 14 to 36 pfennigs, and the state adds a certain amount to this, but the dues and benefits are restricted to wage earners.

increased intracranial tension, but apparently never had the opportunity of using it in the acute ventricular block of cerebrospinal meningitis.

When the operation is performed, a rather wide opening should be made in the corpus callosum by gently moving the cannula. This opening is said to have the tendency to remain patent, and a new, more or less permanent communication is established between the ventricular cavity and the subarachnoid space. Surely this is probable as long as the normal outlets are clogged and as long as the intraventricular pressure is increased. Perhaps the callosal puncture may close after the exudate over the fourth ventricle has been absorbed and the foramina have reopened; but that is quite immaterial, as its object has been accomplished. In fact, as Flexner has suggested, the block in certain instances may not be due to an actual organic obstruction, "but merely to a functional lack of mechanical resistance which permits distention of the ventricles under moderate pressure, eventuating possibly in temporary obliteration of the outlets of the fourth ventricle by weight of the dilated lower horns which press the cerebellum down against the medulla." Under such conditions, a vicious circle would be established—the more distention of the ventricles the tighter the closure, and the tighter the foramina are closed, the more the ventricles will distend. In these functional cases, puncture of the corpus callosum would deliberately break the vicious circle.

We believe that this procedure is life saving in certain cases that would otherwise be hopeless. We also believe that in the nonfatal cases the distressing sequelae of hydrocephalus might be avoided by relieving the ventricular distention sufficiently early. Further, puncture of the corpus callosum is an operation of no great difficulty or magnitude, and can be performed without damaging any really essential structures of the brain. The contention that the injury to the association fibers produces an apraxia is not substantiated by practical experience.

The report of a case is submitted to illustrate our argument:

April 1, 1918, a soldier, aged 19 years, white, admitted to the meningitis ward of U. S. Army General Hospital No. 1, had been sick twenty-four hours, complaining of severe headache, stiffness and pain in the neck, nausea and vomiting. The patient's temperature was 101 F., the pulse 60. On admission, 30 c.c. of turbid fluid under moderately increased tension were drawn off by lumbar puncture, and 20 c.c. of antimeningitis serum were given intraspinally. Examination of the cerebrospinal fluid revealed approximately 2,200 cells per cubic millimeter, mainly polymorphonuclears, and the smear showed a gram-negative diplococcus. The family and the past personal history were negative. The patient appeared moderately ill, but he was mentally clear, and able to sit up and even walk. The pupils were equal, moderately contracted, but responded promptly to light and accommodation. There was no nystagmus. There was slight herpes labialis. The neck was rigid. There was a well marked bilateral Kernig. There was a definite tache cérébrale. There was no involvement of the cranial nerves. There was no Babinski reflex, but the patellar reflexes were slightly exaggerated.

April 2, the patient still complained of severe headache. There was no change in his physical signs. Thirty-five c.c. of antimeningitis serum were given intraspinally. Examination of the spinal fluid revealed 3,600 cells per cubic millimeter, and no organisms nor growth.

April 3, the patient appeared improved; 20 c.c. of antimeningitis serum were given intraspinally. The spinal fluid showed 2,500 cells per cubic millimeter and no organisms.

April 4, 20 c.c. of antimeningitis serum were given intraspinally. Herpes labialis was well marked. There were 400 cells per cubic millimeter in the spinal fluid.

April 5, 35 c.c. of antimeningitis serum were given intraspinally. The patient appeared more comfortable. There were 480 cells per cubic millimeter and no organisms.

April 6, 25 c.c. of antimeningitis serum were given intraspinally. The spinal fluid contained 900 cells per cubic millimeter, with no organisms. There was a faint systolic murmur at the apex.

April 7, the patient had little headache and only slight rigidity of the neck; but Kernig's sign was still marked. There were no cranial nerves involved. On lumbar puncture, 25 c.c. of clear, straw colored fluid were removed containing 210 cells per cubic millimeter, and 20 c.c. of antimeningitis serum were introduced. The temperature was 103.6 F., the pulse 72.

April 8, the temperature ranged from 100.2 to 104 F.; the pulse remained about 72. The patient complained of slight headache and general pains. Herpes labialis was less marked. The rigidity of the neck was not so great. There was a sinus arrhythmia. There were no cardiac murmurs. On lumbar puncture, 40 c.c. of clear, light colored fluid under considerable pressure were withdrawn, and 30 c.c. of antimeningitis serum were introduced. At 2:30 p. m., examination of the fundi revealed slight marginal blurring of both optic disks and moderate enlargement of the retinal veins. A diagnosis of beginning papillitis was made. At 3:30 p. m., the patient developed a very severe headache necessitating the use of 0.03 gm. of morphin. Fifty c.c. of antimeningitis serum were given intravenously.

April 9, at 9 a. m., the headache was less severe, but the rigidity of the neck was very definite. The Kernig sign was about 20 degrees on the right and about 45 degrees on the left side. The knee jerks were diminished. There was no Babinski reflex. At 11:30 a. m., lumbar puncture was performed and 70 c.c. of clear, light colored fluid were obtained and 60 c.c. of antimeningitis serum introduced. The patient had a chill, but the headache became less severe. At 5 p. m., he complained of very severe headache. Lumbar puncture was performed, and 80 c.c. of somewhat cloudy fluid under considerable pressure were withdrawn. At 8 p. m., the patient developed a weakness in the right external rectus, which soon became well marked. The blurring of the disk margins was less noticeable. There was no evidence of involvement of any of the other cranial nerves.

April 10, the general condition was somewhat improved. There were no changes in the physical signs. Sixty-five c.c. of fairly clear fluid were removed by lumbar puncture and 55 c.c. of antimeningitis serum introduced. At 4:45 p. m., the patient complained of a very severe headache and became markedly delirious. The paralysis of the right external rectus was very definite, and the facial muscles of the right side, including the frontalis, were paretic. There was a rough twitching of the muscles of the extremities. The patient yelled every few minutes and sang occasionally. At 6:30 p. m., he had two convulsions about fifteen minutes apart. They involved principally the left side of the face, and there was a conjugate deviation of the head and eyes to the left. He foamed at the mouth and had involuntary passage of feces and urine. At 8 p. m. a lumbar puncture was performed, and 40 c.c. of cloudy fluid were withdrawn. The pressure was very slight as compared with that of the morning. Coughing and straining did not increase the flow, as they had previously done. The temperature was 99 F., the pulse 58. The condition of the patient was extremely critical. Based on previous similar observations, it was concluded (Major Roberts) that the patient was definitely suffering from an acute obstructive hydrocephalus as a result of blocking of the ventricles, and that he should be given some form of surgical relief. A consultation resulted in the decision by one of us (Major Stetten) that the only logical and correct procedure was deliberately to establish ventricular drainage by a puncture of the corpus callosum. This was agreed on.

At 11:50 p. m., the patient was brought into the operating room in a raving delirium. The operation was performed under ether anesthesia (Major Stetten). A trephine opening about 2 cm. in diameter just to the right of the median line and about 1.5 cm. behind the coronal suture was made by means of a Hudson drill and rongeur. A dural flap was formed and the brain was found to be under considerable tension, although there was no evidence of inflammation of the membranes at the convexity of the cerebrum. A blunt, curved, callosal puncture cannula was introduced along the falx cerebri through the median fissure into the right ventricle, and about 25 c.c. of very slightly turbid, blood-stained fluid gushed out. It was decidedly different in character from that last withdrawn by lumbar puncture. The way the fluid flowed through the cannula suggested the manner in which the urine runs through a catheter when the bladder is distended. The opening in the corpus callosum was enlarged by gently moving the end of the cannula. No antimeningitis serum was introduced into the ventricles, as the fluid was not sufficiently purulent. The dura was closed with a chromicized catgut suture. The skin was closed with silkworm gut and a small rubber tissue drain inserted subcutaneously. Examination of the fluid showed it to contain very numerous leukocytes, about 75 per cent. polymorphonuclear. The cells were so clumped that a count was impossible. The culture was negative after seventy-two hours. No organism was found in the smears.

April 11, the patient was semiconscious and perfectly quiet. There was a right peripheral facial palsy. The neck was rigid, and there was difficulty in swallowing. There was no Babinski reflex. Toward evening the patient complained of severe headache and remained confused. The temperature remained low. The general impression was one of improvement.

April 12, the patient had regained consciousness. There was a decided change for the better. There was now a slight paresis on the left side of the face. The right external rectus was still weak, and there was a suggestion of a Babinski reflex on the left side. There was a serum rash on the extremities.

April 13, the patient stated that he ached all over; but he looked much brighter. The pulse was 110 and dicrotic. The finger nails were cyanosed. The paresis of the left external rectus was apparent. In the afternoon a lumbar puncture was performed and about 8 c.c. of blood-tinged fluid obtained, which came drop by drop. There was a rise of temperature to 101.5 F.

April 14, the patient had made considerable improvement, but still complained of slight headache. He was entirely conscious. The sixth and seventh nerve palsies were less marked, and there was a slight amount of blood in the stools.

April 16, the patient was making a gradual recovery, which had been slightly delayed by a febrile reaction with a maculopapular rash starting on the extremities and extending over the trunk, followed on some portions of the body by slowly fading petechiae, probably anaphylactic phenomena. As the condition of the patient improved, the primary bulging at the cranial defect gradually subsided. About two weeks after operation, there was an actual depression. The wound healed by primary union. The facial and left external rectus palsies disappeared rapidly, and the right external rectus paralysis was gradually disappearing.

May 5, the patient was allowed up for the first time.

May 14, eye examination revealed a slightly larger left pupil and a moderate convergence of the right eye. The pupils reacted normally to light and accommodation. Vision was 20/20 in both eyes. Both fundi were normal, and the optic disks were of good color and well outlined. The function of the right external rectus was returning, and at present represented a power of external rotation of about 15 degrees. The visual fields were normal.

May 18, the patient had been up for two weeks, and the temperature had been normal for three weeks. He was sent on furlough to his home.

A recent inquiry has elicited the information (October 2) that he returned to duty about August 1. His only complaint had been pain in his legs, which has gradually subsided. He has been riding a motorcycle and is now going in for football. The right external rectus has entirely recovered its function, and his mental and physical condition is in no wise impaired. He is anxious to go overseas, but he has been put in the domestic service class, presumably on account of the cranial defect.

SUMMARY

In the foregoing we find that a case of epidemic cerebrospinal meningitis, which had been running a relatively normal course, rather suddenly develops signs and symptoms pointing to an acute obstructive hydrocephalus. The patient rapidly goes into a condition that is little short of moribund, and a puncture of the corpus callosum to establish ventricular drainage is deliberately decided on and performed. The fact that the fluid from the ventricles was entirely different in character from the last fluid by lumbar puncture, and the manner in which the fluid gushed from the cannula, proved conclusively that the diagnosis of ventricular block was verified. Examination of the ventricular fluid showed no evidence of active meningococcic inflammation within the ventricles. The immediate postoperative improvement in the patient was almost miraculous, and is hard to realize by one who did not actually observe the change. The subsidence of the protruding intracranial contents shortly after operation, as the patient's condition improved, corroborated the view that the recovery, which eventually became complete, was due to the relief of the ventricular distention. We feel that we are justified in advocating puncture of the corpus callosum for ventricular drainage as a rational, life-saving procedure when the clinical picture of ventricular obstruction, described and illustrated above, appears in the course of a cerebrospinal meningitis.

In such cases, when, in addition to ventricular blocking, there appears to be an actual infection of the ventricle, that is, when the ventricular fluid is turbid or frankly purulent, or when diplococci are found in the smear, intraventricular administration of antimeningitis serum should be combined with puncture of the corpus callosum. Care must be observed to inject less serum into the ventricles than the amount of fluid withdrawn.[23]

Roentgen Examination of Gas-Filled Abdomen.—The *Nederlandsch Tijdschrift* cites a recent article by O. Goetze lauding the instructive *findings* when oxygen is allowed to pour into the abdomen preliminary to roentgen examination. This, he says, is entirely harmless, while it shows the viscera, diaphragm, etc., more clearly than ever before seen.

CARDIOVASCULAR EXAMINATIONS OF RECRUITS

AT CAMP LEWIS MUSTERING OFFICE, APRIL 20 TO OCT. 1, 1918

DONALD CASS, A.B., M.D.
First Lieutenant, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

Cardiovascular examinations of recruits at Camp Lewis from April 20 until July 20, 1918, were made only on men referred either by the tuberculosis examining board for abnormalities noted on routine chest examination or by the mustering office during general examinations. This method of referring cases was very unsatisfactory, as was shown by the large number of cardiovascular patients, found to be unfit for service after mustering in, who had never been referred to the cardiovascular examiners.

The announcement that 12,000 men would enter camp in July, and that each month thereafter a similar number would probably be sent, made it necessary to increase the efficiency of the cardiovascular examining board and especially to find a better method of referring men to the board.

The following plan was adopted: A board was organized which was composed of twelve medical officers and a corps of enlisted personnel. Nine officers were assigned for temporary duty during the incoming draft, and together with the three permanent cardiovascular examiners composed the board, the permanent specialists being used as a nucleus for the organization.

This board of medical officers was divided into two groups, preliminary and refer examiners. The duty of the preliminary examiners was to examine all the recruits before and after exercise and to recognize enlarged thyroids as well as abnormalities in the cardiovascular system. Refer examiners made complete cardiovascular examinations of men in whom abnormalities were noted by the preliminary examiners.

Five of the more experienced medical officers were made preliminary examiners and stationed in the upper story of the barracks used by the special examining boards. Any abnormality is noted on a slip of paper, the men are marked "C. V." with a skin pencil and sent to refer examiners downstairs, where in quiet rooms the routine complete examinations are made, including the hopping test as prescribed.

The work of the preliminary examiners is extremely important and, we think, efficient. Recruits are examined in groups of forty, stripped to the waists, lined on spots on the floor. Each officer examines eight men in each group, first rapidly passing down the line noting the location and character of the apex impulse and auscultating at all four valvular areas. Under the direction of an enlisted drill master the men are then exercised, bending forward and touching the floor rapidly forty times, keeping the knees stiff. (This exercise was used because it was noiseless and vigorous). The examiners again pass down the rows of recruits, this time more carefully, observation, palpation and auscultation being used. The purpose of the first preliminary examination is to cause those with dangerous defects to drop out without being subjected to too vigorous drill.

Recruits in whom cardiovascular defects have been noted are sent to the refer examiners downstairs. Here the history form is filled out, the pulse counted standing and supine, the men are made to hop 100 times on the left foot, and the pulse is counted in the supine position immediately and again after two minutes. This work is all done by enlisted clerks. Pulse records taken by clerks were probably more accurate than would have been if made by officers, as the men were chosen for this work and coached till they were very accurate; also conditions of pulse taking are maintained at a uniform standard. The medical officers now complete the examination. Fluoroscopy is performed in the same building by experts from the camp base hospital and tuberculosis examining board.

TABLE 1.—COMPARISON OF DISPOSITION OF RECRUITS

		Referred		Accepted			Rejected		
System	Draft Total	Total	% of Draft	Total	% of Draft	% of Refer.	Total	% of Draft	% of Refer.
1. Old.....	40,851	2,474	6.0	2,063	5.0	83.4	411	1.2	16.5
2. Present	30,697	4,213	13.7	3,340	10.8	79.3	873	2.8	20.7

Goiter examinations were conducted by a specially assigned medical officer with his own group of clerks during the July draft, but the examination of a large number of goitrous men, as reported by Capt. Thomas Addis, M. C., and Capt. W. J. Kerr, M. C.,[1] of this board in a previous paper, showed that in spite of the fact that endemic goiter is very prevalent in recruits reporting to Camp Lewis, toxic symptoms are extremely rare. Therefore in the August draft this special goiter examination was omitted. Those men with moderately or greatly enlarged thyroids were noted and those rejected in whom sufficient tumor was present to prevent use of the regulation military uniform without alteration of the collar, and also those presenting definite pressure symptoms, as well as marked substernal thyroids. The goiter notations were made during the routine cardiovascular examinations.

TABLE 2.—PROBABLE RESULTS UNDER PRESENT SYSTEM AS COMPARED WITH RESULTS UNDER OLD SYSTEM

		Rejected	
	Total Recruits	Per Cent.	Number
1. Results under old system............	40,851	1.2	411
2. Probable results on same men under present system	40,851	2.8	1,144
Difference..................................		1.6	733

The figures obtained by the cardiovascular examiners are given in Table 1, comparing the disposition of cases before the installation of the present system, including an increment of 40,851 men, and under the present system, 30,697 men. Analysis of the table shows an increase of more than 100 per cent. in the number of men referred and a corresponding increase in the number rejected. This means that the physical condition of drafted men being the same in both groups, 505 men were rejected under the present system who would have been missed by the old method, and 733 were accepted while the old system was in vogue who were suffering from disqualifying defects

TABLE 3.—PROBABLE RESULTS UNDER OLD SYSTEM AS COMPARED WITH RESULTS UNDER PRESENT SYSTEM

		Rejected	
	Total Recruits	Per Cent.	Number
1. Probable results under old system...	30,697	1.2	368
2. Results under present system........	30,697	2.8	873
Difference..................................		1.6	505

and who would have been detected and rejected by the present board (Tables 2 and 3).

The most obvious thing shown by Table 4, the diagnosis tabulation, is the large relative and absolute increase in the number of certain types of abnormalities noted, especially cardiac murmurs, mitral insufficiency, mitral stenosis and irritable hearts. The increase of apical systolic and decrease in pulmonic systolic functional murmurs resulted from the more strenuous method of exercise used, which we find tends to bring out murmurs at the apex while those at the base tend to disappear.

The detection of a greater number of mitral insufficiency and stenosis cases and those of mitral stenosis is due also to the improved exercise, as it is well known that presystolic and diastolic murmurs many times are heard only after violent exercise.

TABLE 4.—DISPOSITION OF CASES BY DIAGNOSIS*

Diagnosis	April 20 to July 20			July 20 to October 1		
	Accepted	Rejected	Total	Accepted	Rejected	Total
1. Normal hearts	900	0	900	937	0	937

36. Pulmonic lesion	0	1	1	0	0	0
37. Elephantiasis	0	1	1	0	0	0
		400 11†	2,463 11†			
Total	2,063	411	2,474	3,336	873	4,209

* Four cases accepted with waiver of disability are not included in the list.

† Eleven cases classified as combined lesions were recorded in whom duplicate records were not kept and the exact diagnosis is not obtainable.

Increase in the number of cases of irritable heart (neurocirculatory asthenia) was due to the more careful observation by the preliminary examiners. All cases in which an abnormally high pulse rate was noted after exercise or in whom objective symptoms, such as undue dyspnea or faintness, were observed were sent to the refer examiners. We have been enabled also to detect many cases of acute infectious disease before the onset of subjective symptoms, tachycardia without history of previous trouble putting us on our guard. In these cases, temperature was taken; and if it was above normal, the recruit was isolated and sent to his infirmary. If the man complains of fatigue due to a long, arduous trip to the camp, he is given a rest, a good night's sleep, and his pulse is counted again on the following day.

Attention will probably be brought to the large number of men with mitral insufficiency accepted for full duty. These men show the characteristic murmurs with no cardiac hypertrophy, very slight or no accentuation of the pulmonic second sound, and no history of recurring attacks of acute rheumatic fever, chorea or tonsillitis. The apex beat is well within the nipple line and of normal character; the pulse and reaction to exercise are normal; the systolic murmur at the apex is transmitted well into the axilla; there is a systolic murmur at the mitral area, and the pulmonic second sound is more distinct than the aortic but is not definitely accentuated. These men are not classified as rejects in the recruiting regulations and have been accepted for full military duty. A list has been made of all these men, and I am at work at present preparing a report of their final disposition, especially as to their ability to undergo severe continued physical strain, such as given in the intensive training in camp.

CONCLUSIONS

1. The system of referring recruits for supposed cardiovascular defects by a mustering board or tuberculosis board when abnormalities are detected during the course of other examinations is entirely unsatisfactory. At least 50 per cent. of men coming to camp with disqualifying cardiovascular defects are not detected by this method.

2. A system such as the one in vogue at Camp Lewis, whereby every recruit is given a special cardiovascular examination, is efficient and should be instituted in all camps receiving large draft increments.

EFFECT OF CARDIAC DISTRESS ON THE WORK OF RECRUITS

GORDON E. HEIN, A.B., M.D. (PUEBLO, COLO.)
Lieutenant, M. C., U. S. Army; Examiner in Cardiovascular Diseases
CAMP SHERMAN, CHILLICOTHE, OHIO

Physically, an army, like a chain, is only as strong as its weakest part. Each individual link or element in the make-up of the soldier-to-be is examined by the orthopedic, neuropsychiatric, tuberculosis, cardiovascular, genito-urinary and other examiners. On their arrival at Camp Sherman, the recruits pass before the different examiners, and the manifestly unfit are rejected. The tuberculosis examiners make a cursory examination of the heart. The apparently normal are passed. Those showing any abnormality are referred to the cardiovascular examiners. Here they are examined more carefully, from ten to fifteen minutes, or more when necessary, being devoted to each case. As a rule about 3 per cent. are referred to this board, a varying number of whom are accepted. The organic valvular diseases give little trouble, as the rules governing this type of case are more or less definite. The same group of cases that offers trouble in the examining line causes the greatest difficulty when more time is given for examination. We refer to the individuals complaining of some dyspnea, some cardiac distress or pain, and showing a rapid pulse, a poor response to exercise, often blue, cyanotic hands and feet, profuse sweating, especially in the axillae, a coarse, irregular tremor, and apparently little change in the heart. What becomes of the milder cases when accepted?

Three hundred men returned to the development battalion from the various line organizations because of complaints of "heart trouble" throw some light on this problem. The men, passed as apparently normal, were placed in organizations, found unable to drill, rejected as unfit for full military service, and referred to the development battalion.

OCCUPATION

As shown in Chart 1, the largest number of cases occurred among farmers, with laborers next, the two classes forming 168 cases, or 56 per cent. of the total. The clerical positions came next, with 17 per cent. The remainder were fairly evenly scattered. Sedentary occupations seemed to have little to do with the cases referred to the development battalion.

HISTORY OF PAST ILLNESSES

Chart 2 shows the relative frequency of the past illnesses. In every case the disease was named, the man answering "yes" or "no" to the inquiry. Whether measles and whooping cough are so common, or the familiarity with the names caused the men to believe that they had had the diseases in the past, is an open question, although all answers seemed to have been given in good faith. Excluding measles and whooping cough, acute rheumatic fever was the most common illness, 33 per cent. of the men giving a definite history of swollen, tender joints, with the acute process going from one joint to another. Occasionally, there were men who dated their trouble back to an acute infection. The acute infections of scarlet fever, typhoid fever, pneumonia and tonsillitis have about the same frequency, while the considerable number of men from the South raises the malaria incidence.

It is interesting to note that 154 have had symptoms for five years or more, some insisting that they have always had distress. Among those who have had trouble for six months or less, only twenty-three in all, most attribute their difficulty to an acute infection.

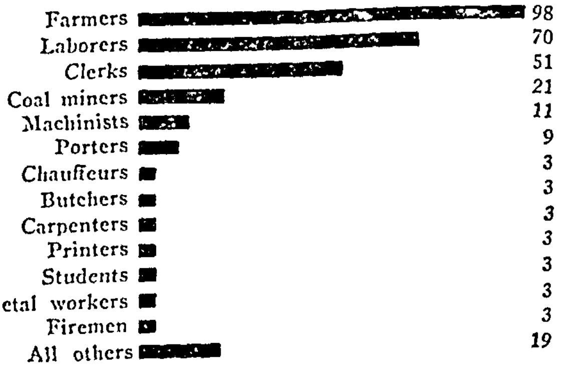

Chart 1.—Relative occupations.

As would be expected in youths of this age, the use of tobacco is almost universal, 253 out of 300 using it in some form or another. Alcohol also has its share of followers, two thirds using it as a beverage, some to excess. Whether these proportions are high for males of this age it is impossible to state.

PRESENTING SYMPTOMS

Giddiness, present in 242 cases, was the most common symptom. It was especially noted on sudden stooping or change of position, when drilling in the hot sun or when standing at attention, and was a frequent cause of dropping out of line at drill or when on a hike. As a rule it was momentary and was relieved by a short period of rest.

On prolonged effort or on sudden severe effort, dyspnea occurred in 239 instances. A hike or double quick time sent these men out of formation in short order. On hopping 100 times, a few showed marked dyspnea; but as a rule it was slight or of moderate severity. However, it seemed to be very troublesome, and "shortness of breath" was the complaint that sent many to the surgeon.

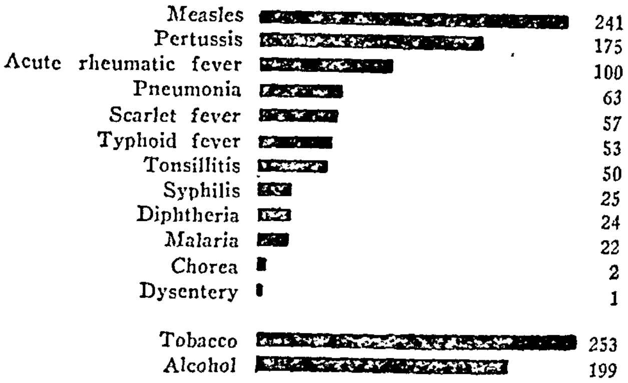

Chart 2.—Relative frequency of illnesses in the past.

Palpitation occurred in 218 out of the 300 cases.

Forty-seven gave a history of fainting. This does not include those with a single syncopal attack, but only those in which there was a history of repeated attacks.

In 154 there was a cough, which seems to be a common complaint among the recruits.

Varied complaints were received, but the foregoing seemed to be a group that persistently ran through the 300 cases.

PHYSICAL FINDINGS

The physical findings were interesting. Among the 300 men returned to the development battalion, 19 had hypertension with hypertrophy; 12, myocarditis; 9, mitral insufficiency; 8, hyperthyroidism; 5, aortic insufficiency; 4, hypertrophy of uncertain etiology; 3, mitral stenosis, and 1, tuberculosis.

This leaves 239 of the original 300 who belong to the large group of the so-called persistent tachycardias, certainly an important group. Two hundred and forty-eight were white, and fifty-two were colored. The average weight was between 120 and 150 pounds, with 190 between these limits. The extreme varied from 100 to 205 pounds. Cyanosis of the hands and feet occurred in 142, and a coarse, irregular tremor of the hands was present in 175 instances. The heart showed enlargement only when definite organic disease could be demonstrated. The apex beat was diffuse in 108 cases. A presystolic thrill was present in three cases of mitral stenosis, but was not demonstrated in any of the "persistent tachycardias." A definite systolic thrill occurred in six cases, although an indefinite suggestion of one was present in some of the rapid overacting hearts. The heart tones were distant in twenty-two instances, and in fifty-nine the first tone at the apex had lost its muscular element and was approaching the second tone in quality. The first tone at the apex was reduplicated in eight cases, and the second tone at the base twice. A systolic murmur was heard at the apex in 118 individuals, and at the pulmonic area in forty-one.

The three mitral stenosis lesions revealed presystolic murmurs over the apex, while over the third left interspace the diastolic blow of aortic insufficiency was found five times. A cardiorespiratory murmur was discerned nine times. A definite respiratory sinus arrhythmia was present in twenty-one cases, and premature systoles occurred in nineteen of the 300 cases. The systolic pressure fluctuated between 110 and 280, while the diastolic was more constant, varying between 80 and 100 mm. of mercury. With the exception of the broader top of the systolic curve, the two curves resemble one another quite closely (Chart 3).

An extremely interesting finding was the high percentage of the men who were returned with an enlargement of the thyroid gland. Many men coming to this camp were recruited from Ohio, Indiana and Illinois, or the so-called goiter belt about the Great Lakes. Many of these cases were passed as simple goiter and sent to the line organizations. Out of the 300 men that were returned to the development battalions because of cardiac distress, eighty-six, or 28.6 per cent., showed a definite enlargement of the thyroid gland. Eight were classed as instances of hyperthyroidism, as they presented an enlarged gland, a fine tremor, tachycardia, exophthalmos, sweating, flushing, a high pulse pressure, and other symptoms accepted as an expression of a toxemia due to an excessive, or a deranged, secretion of the thyroid gland. In seventy-eight, the thyroid was enlarged without question, the heart was rapid, a coarse, irregular tremor was evident in the hands, which were often cyanotic, and sweating in the axillae was profuse; but no exophthalmos, no fine tremor and no history of alimentary disturbances could be obtained, so that these cases were not the typical accepted textbook thyroid intoxications, but, certainly, the large number returning suggested that the so-called simple goiters may be potentially or actively toxic, or at least that the men who have the so-called simple goiters do not stand intensive training well.

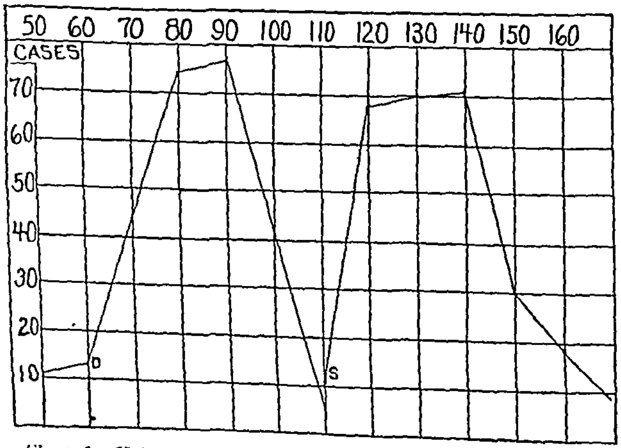

Chart 3.—Height of blood pressure in millimeters of mercury: *D*, diastolic; *S*, systolic.

A definite thyroid enlargement can easily be seen on the first examination, and if not classified, at least a notation should be made so that the individual may be kept under observation by the battalion or regimental surgeon.

The nervous element sometimes predominates in the individuals with a persistent tachycardia. Out of 100 cases classified by the heart examiners, twenty were also under observation by the neuropsychiatrists, who were doing their work independently in another part of the building. The accompanying table shows how the various diagnoses run in a series of such cases.

Probably some of the tachycardias will be eliminated through examination by other examiners, who may find the basis for the rapidity of the heart, which must be considered a symptom and not an entity. It is probable that neurologic conditions as well as some of the thyroid cases or endocrinopathies are classed among the so-called neurocirculatory asthenia cases. Many of the patients with persistent tachycardia complain of identical symptoms and present the same clinical picture. The diagnosis of neurocirculatory asthenia could be used to cover a large number of cases in which the eitology is uncertain, and, indeed, may be a group of conditions instead of a well defined clinical entity. Mackenzie says:

CARDIOVASCULAR AND NEUROPSYCHIATRIC DIAGNOSES IN PATIENTS WITH PERSISTENT TACHYCARDIA

Initial of Patient	Cardiovascular Diagnosis	Neuropsychiatric Diagnosis
J. N.	Simple tachycardia	Traumatic neurosis

> It has already been pointed out that when the heart is forced to do work beyond its normal capacity, or, in other words, after the reserve force has been exhausted, sensations of distress arise. The sensations may vary, at first, a slight breathlessness, a sensation of suffocation referred to the throat, or a tightness across the upper part of the chest. These are the signs usually experienced by healthy people whose hearts have for the time being been subjected to a severe strain. In addition to these sensations, pain may be induced, and be followed by other sensory disturbances, as hyperalgesia of the skin and subcutaneous tissues of the left chest wall.

In the group of men referred to the development battalion, the 239 cases showing a tachycardia showed a systolic-diastolic rate or energy index, as described by Barach, consistently over 20,000. Add to this the work put on a heart by the intensive training of the military routine, and one can readily see why a certain number complain of "heart trouble."

SUMMARY

1. Few organic valvular heart lesions escape during the routine examination of recruits.
2. Men with persistent tachycardia due to various causes form the largest group slipping by the examiners, later to return unable to perform full military duty.
3. The number of alcohol and tobacco users among those complaining of cardiac distress seems high. Sedentary occupation seemed to have little to do with the cases examined here.
4. A large number of men with enlarged thyroid glands develop cardiac symptoms when put under severe physical strain. Soldiers with enlarged thyroid glands should be kept under observation.

5. A certain percentage of the persistent tachycardias are fundamentally nervous conditions and can be eliminated by the neuropsychiatrists.

6. The persistent tachycardias are a group of conditions, the etiology of which must be determined before a rational plan of treatment can be prescribed.

RELATION OF METEOROLOGICAL CONDITIONS TO THE PREVALENCE OF PNEUMONIA

DAVID GREENBERG, B.S.
Instructor in Public Health, Yale University School of Medicine
NEW HAVEN, CONN.

While there seems little doubt that meteorological conditions have a distinct influence on the occurrence of pneumonia, and although a good deal of investigation has been carried on in the endeavor to throw light on this relationship, yet there is still a considerable lack of unanimity of opinion in our present views regarding this connection.

Concerning the relation of season to pneumonia, it is apparent that the greatest incidence from this disease occurs during the cold months. Seitz[1] showed that for a period of twenty years in Munich, 37 per cent. of the cases occurred in the spring, 32 per cent. in winter, 16 per cent. in autumn and 15 per cent. in summer. Anders[2] found the incidence in Philadelphia for a period of ten years to be: first quarter, 43.2 per cent.; second quarter, 24.5 per cent.; third quarter, 9.6 per cent., and fourth quarter, 22.8 per cent. Analyses that I have made of the deaths from lobar pneumonia in New York City for the years 1901 to 1915 show, for the first quarter, 38.1 per cent.; second quarter, 25.8 per cent.; third quarter, 10.9 per cent., and fourth quarter, 25.3 per cent. The monthly incidence is shown in Table 1, from which it will be seen that the maximal number of deaths occurs in March and the minimal number in August.

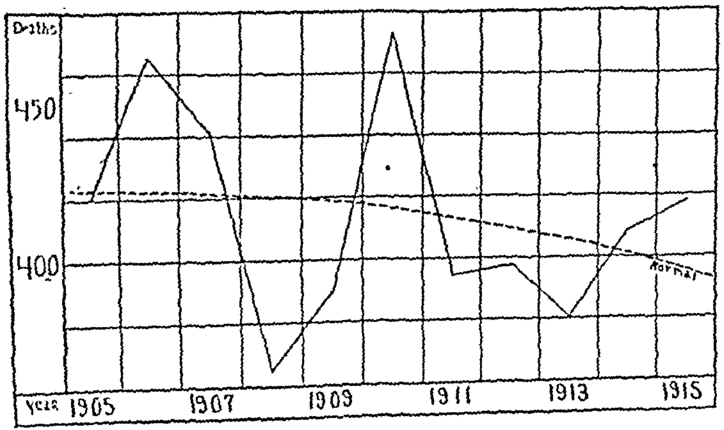

Chart 1.—Annual number of deaths and normal number of deaths from pneumonia, Providence, R. I., 1905-1915.

It was long recognized that temperature alone altogether fails to explain increases and decreases in the pneumonia death rate, and the answer was sought for in other meteorological conditions. As to the relation of temperature changes or variability, Aufrecht[3] found the incidence of pneumonia to be directly dependent on the prevalence of unequal and changeable meteorological conditions, especially on the occurrence of abrupt and marked changes of temperature at a time when the mean temperature was very low. Anders contends that abrupt oscillations of temperature per se have a restricted influence, if any, as a favoring factor. On the other hand, Fraenkel[4] has pointed out that, in certain localities (London, Dublin, Wurzburg and Tübingen) most of the pneumonia cases occur during those winter months in which, while the actual temperature is lower, yet the daily variation is less than during the spring.

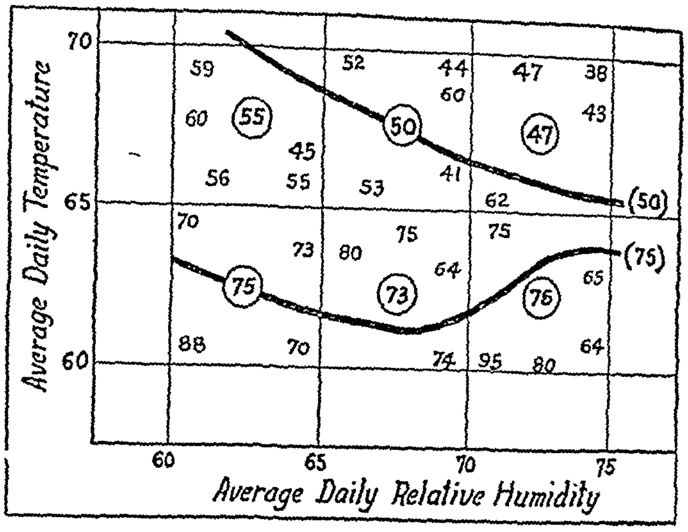

Chart 2.—Method of constructing the climograph: A sheet of ruled paper is divided into squares, each square corresponding to a certain combination of temperature and humidity, one square, for example, for a combination of temperatures between 60 and 65 F. and humidities between 60 and 65 per cent. The percentage mortality for each month is then recorded in the proper square determined by the combination of temperature and humidity prevalent for that month. The values recorded within each square are then averaged, and the resulting value is indicated within the small circle. Thus, 75 is the average percentage of mortality for months having a temperature between 60 and 65 degrees and a humidity between 60 and 65 per cent. Points of equal value from the standpoint of percentage of mortality are then joined by lines. Thus, the upper sloping line on the diagram is intended to pass through all points having a value of 50 per cent. In the middle square, the line passes through the point 50; but in the square to the left, having a greater value than 50, the line passes above this point, while in the square to the right, it necessarily must pass below the value of 47. The lower line, which is supposed to pass through all points having a value of 75 per cent., will be noted to pass below the value 73 (central square) and above the value of 76 (square on the right).

TABLE 1.—DEATHS FROM LOBAR PNEUMONIA, BY MONTHS, IN NEW YORK CITY (1901-1915)

Month	Deaths	Month	Deaths
January	11,331	July	3,259
February	10,555	August	3 021
March	11,943	September	3,358
April	10,103	October	4,582
May	7,974	November	7,101
June	4,704	December	10,448

Concerning the influence of relative humidity Riebe[5] believes that a contributing cause of pneumonia (in Posen) is found in excessive humidity. Baker[6] noted a slight correlation between a low absolute humidity and a low pneumonia incidence. Anders, who studied this matter in detail, does not come to any definite conclusion on this point.

In regard to the effect of barometric pressure, Jurgensen[7] maintains that a high barometer is coincident

with a diminished prevalence of the disease. Anders found that those months in which the highest death rate occurred showed maximal monthly barometric range; and vice versa, those months showing minimal barometric range gave the lowest death rate.

The influence of winds on pneumonia incidence has not been definitely established. Anders maintains that the direction of the wind (northwest) bears a close relation to the period of maximal mortality from pneumonia.

From this brief summary it is to be seen that the evidence presented by investigators is conflicting.

While engaged in an investigation of death rates from pneumonia in cities in New England and the North Atlantic states, I noted that these were markedly higher than those for cities in the interior or on the Pacific Coast. Having in mind the prevailing opinion that pneumonia is favored by a moist condition (dampness and cold), I desired to see whether the high rates in the cities along the Atlantic seaboard could be explained on this basis.

After an extended analysis of the more important meteorological conditions (relative humidity, temperature, wind, rainfall and barometric pressure) of the group of seaboard cities, and comparison with a group of inland lake cities (with low pneumonia death rates), no striking or significant points of difference between these two groups could be detected as far as their climatic factors are concerned.

TABLE 2.—WORKING SHEET FOR THE CONSTRUCTION OF CLIMOGRAPH FOR PROVIDENCE, R. I.

Year	Annual Mortality Recorded	Annual Normal Mortality	Monthly Normal Mortality	Actual Monthly Mortality in Percentage of Monthly Normal Mortality											
				January	February	March	April	May	June	July	August	September	October	November	December
1905	420	422	35	188	197	215	109	109	74	26	3	40	49	80	111
1906	466	422	35	137	157	217	223	128	54	54	26	31	80	74	149
1907	440	421	35	203	231	168	100	71	68	63	20	57	60	97	123
1908	363	420	35	217	194	168	117	68	34	17	23	20	49	63	66
1909	389	418	35	128	194	157	103	68	46	60	43	34	54	106	117
1910	473	416	35	200	174	220	191	114	74	49	28	14	55	100	128
1911	395	412	34	132	162	182	170	85	59	41	29	41	76	85	94
1912	398	409	34	150	180	180	117	82	65	53	29	50	65	79	121
1913	379	405	34	150	165	147	100	71	53	50	41	50	65	88	135
1914	408	401	33	215	194	167	200	64	48	36	33	42	76	73	88
1915	417	398	33	137	127	252	267	76	64	39	15	33	39	82	134

It is to be remembered that in dealing with so complex a problem as pneumonia, one city cannot strictly be compared with another, because of the many contributing factors. Such elements as social and housing conditions, and the race and age distribution of the population, are important controlling forces in determining a death rate. It was decided, therefore, to study the climatic factors separately in each city and then to compare these city by city. This plan was undertaken, and the methods used in the past by investigators in this field were followed; but after extended studies, again no significant results were obtained. At this time I was fortunate in hearing of a new method of plotting such records, devised by Prof. Ellsworth Huntington, research associate in geography at Yale University; and adopting this procedure, I began the investigation anew.

It should be stated at the outset that with the exception of one city (Providence, R. I.), the deaths studied are those for lobar pneumonia only (exclusive of bronchopneumonia). The reason for excluding the latter condition is that so many cases of the acute communicable diseases (diphtheria, measles, scarlet fever and whooping cough) terminate in bronchopneumonia that in order to get a true picture of the incidence of lobar pneumonia one should avoid complication by this group of diseases.

METHOD OF MAKING CLIMOGRAPH

Professor Huntington's method for the statistical study of the climatic effects depends on the use of a graph which he calls the climograph—a diagram representing the effect of climate on man. A brief discussion of the construction of the climograph is here given, and those desiring more details must be referred to his original article.[8]

The deaths are first recorded by months of occurrence. Allowances must be made for the varying number of days in different months, and hence a correction must be made. Thus, for February the correction is $^{31}/_{28}$, and for months of thirty days it is $^{31}/_{30}$. The yearly totals are then plotted, and a smooth curve is drawn through these points (Chart 1). From this it will be seen that a normal curve for the period is obtained, representing the conditions that would result if the fluctuations from year to year did not occur.

We are now interested in observing how one year differs from the other as regards mortality, and in order to obtain this difference we note to what extent any particular year is above or below the normal. Obviously, the difference between the recorded number and the normal number of deaths is ascertained by measuring the distance between the two curves. After the normal annual mortality has been determined from the curve, the division of this figure by 12 will give the normal monthly mortality (Table 2). The normal monthly values are then compared with the monthly values as actually obtained from the death returns, which are expressed as a percentage of the normal. These percentages are then plotted against temperature and relative humidity for the corresponding months.

After the percentages are recorded they are grouped in 5-degree intervals of temperature and humidity, and the average mortality of all months having a certain combination of temperature and humidity is determined. For instance, in Chart 2 in the interval corresponding to a temperature from 60 to 65 degrees and relative humidity from 60 to 65 per cent., the percentages when grouped and averaged give a value of 75. A line is then drawn through points of approximately equal value as to average mortality. This procedure corresponds to the drawing of isothermic lines, and the line in this instance might be called an isolethal line. Chart 2 shows in detail the method of construction of the climograph.

[8] Huntington, E.: World Power and Evolution, New Haven, Yale University Press, 1918.

RELATION OF PNEUMONIA TO RELATIVE HUMIDITY

Chart 3 shows the relation of pneumonia to relative humidity for New York City plotted as indicated above. The sloping lines have been drawn in this case as in the other diagrams, through points having a value of 50, 75, 100, 125, 150 and 175. Thus, the 50 line means that it passes through all points that show a death rate of 50 per cent. below normal (the normal being 100). Similarly, the 125 line passes through all points that show a death rate of 25 per cent. above the normal

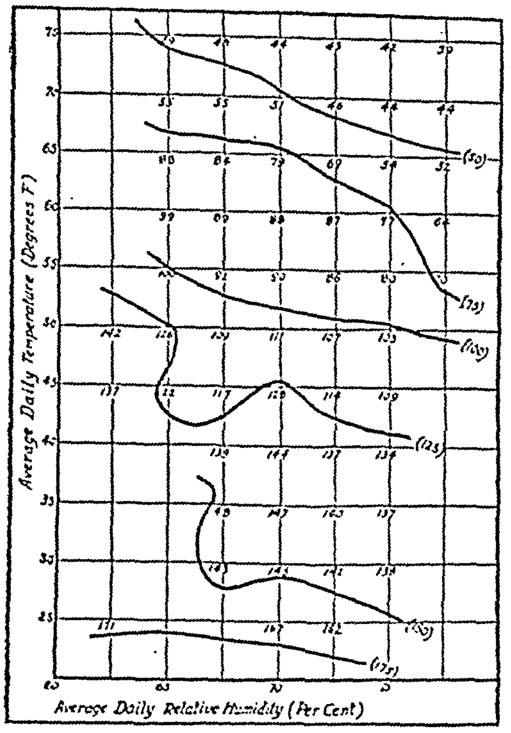

Chart 3.—Relation of daily temperature and relative humidity to the prevalence of pneumonia in New York City, 1901-1915. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

Again, the area between the 75 per cent. line and the 100 line means that on an average the deaths in months having any of the combinations of temperature and humidity falling between these lines range from normal to 25 per cent. *less* than normal. The area between the 100 line and the 125 line means that the deaths falling between these lines range from normal to 25 per cent. *more* than normal.

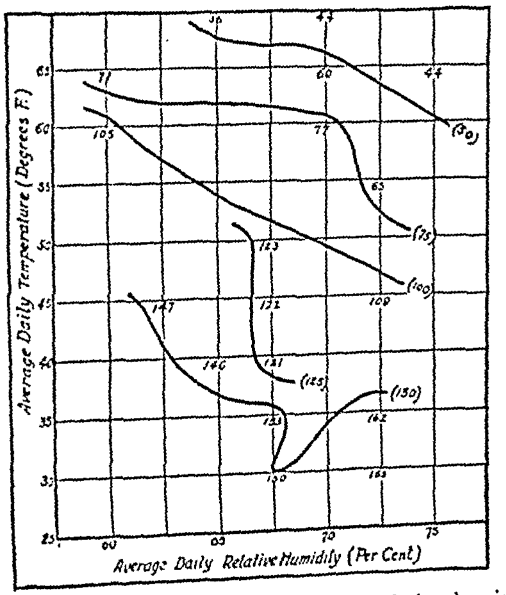

Chart 4.—Relation of daily temperature and relative humidity to the prevalence of pneumonia at Newark, N. J., 1906-1915. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

It is to be noted that all of these lines are nearly parallel. The bend in the 125 line is accounted for by the fact that two exceptionally high figures occurred at that point, which had a tendency to increase the value. It is further to be noted that the direction of these lines is downward, and it is this fact which is most significant. This is interpreted to mean that at a high relative humidity more favorable conditions obtain. For instance, it will be seen that the 125 line extends from 53 F. and 63 per cent. relative humidity to 40 F. and 77 per cent. relative humidity. In other words, the same death rate obtains at a colder and more moist condition than at a warmer and drier condition, in spite of the fact that, as is well known, the largest number of deaths occur during colder periods. This relationship, it will be seen, occurs for every line. The bottom line is somewhat flatter, but this is due to the relatively fewer observations for that area. The same thing can be seen by reading the values horizontally from left to right. Here again, with very few exceptions the values (percentage mortality) decrease as the humidity increases. For instance, it will be noted that with a temperature of 50 F. and with 62 per cent. relative humidity, the percentage mortality is 142, that is, 42 per cent. greater than normal. As we pass to the right (that is, as the relative humidity increases), the percentage mortality decreases. Thus, with 70 per cent. humidity (and a temperature of 50 F.), the percentage mortality is 111; and with 78 per cent. it is 100.

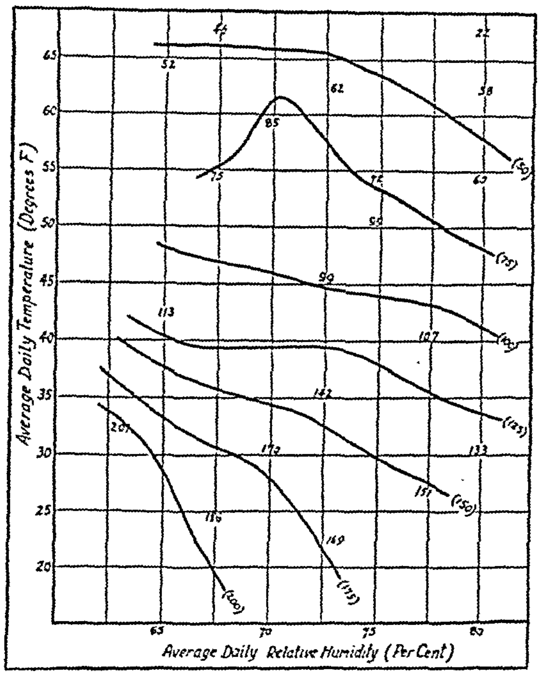

Chart 5.—Relation of daily temperature and relative humidity to the prevalence of pneumonia at Providence, R. I., 1905-1915. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

The conclusion which may be drawn from this chart is that for New York City at any given temperature fewer pneumonia deaths will occur under conditions of high relative humidity than at the same temperature with a low relative humidity.

Charts 4 and 5 show the results obtained for Newark, N. J., and Providence, R. I. It will be noted that here again the relations of pneumonia to relative humidity are similar to those observed for New York

City. Since these curves show such a close similarity, it is fair to combine them; and for this purpose the average values for each city have been properly weighted. The net result (that is, a composite picture weighted and smoothed) is shown in Chart 6. The same type of curve is of course obtained, namely, an oblique line. The irregularity in the 150 line is due to two exceptionally high values observed for New York City. Here, too, it will be seen that the values decrease from left to right, indicating that in cool weather, for instance, moist conditions are better than dry. In this respect the graph is surprising, for it is usually supposed that dry weather is best.

From a statistical standpoint it is to be noted that this curve represents a total of 516 observations of relative humidity and a total of 108,122 deaths, a large enough unit on which to base a deduction. It is safe, therefore, to conclude that for the cities under observation, a high relative humidity is a more favorable condition for a low pneumonia death rate than is a low relative humidity.

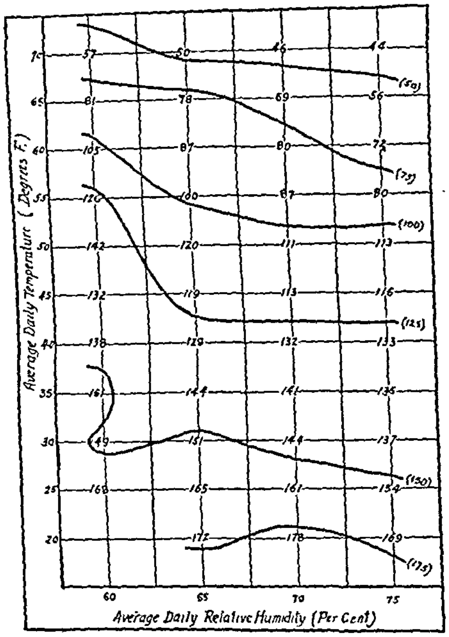

Chart 6.—Relation of daily temperature and relative humidity to the prevalence of pneumonia: Composite of New York City, Newark, Boston and Providence. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

RELATION OF PNEUMONIA TO TEMPERATURE VARIABILITY

It will be recalled that there has been a great diversity of opinion in regard to the part that temperature changes play as a factor influencing the prevalence of pneumonia. Anders maintains that abrupt oscillations of temperature have a restricted influence, and it should be pointed out that the negative result obtained by him is most likely due to a faulty measure of variability which he adopted. For his measure of temperature fluctuation he took the difference between the monthly mean maximal and monthly mean minimal temperature. Obviously, this monthly average figure does not reveal the true temperature changes from day to day. A more exact measure of temperature variability which shows the variation from day to day is the fluctuation of the mean *daily* temperature; and though its study is a very laborious procedure, this measure was adopted in obtaining the results to be described below.

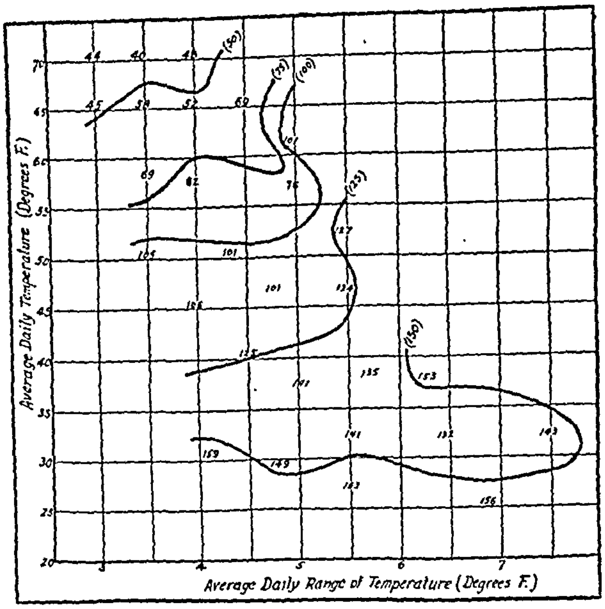

Chart 7.—Relation of daily temperature and daily range of temperature to the prevalence of pneumonia in New York City, 1901-1915. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and daily range of temperature expressed as a percentage of the annual average.

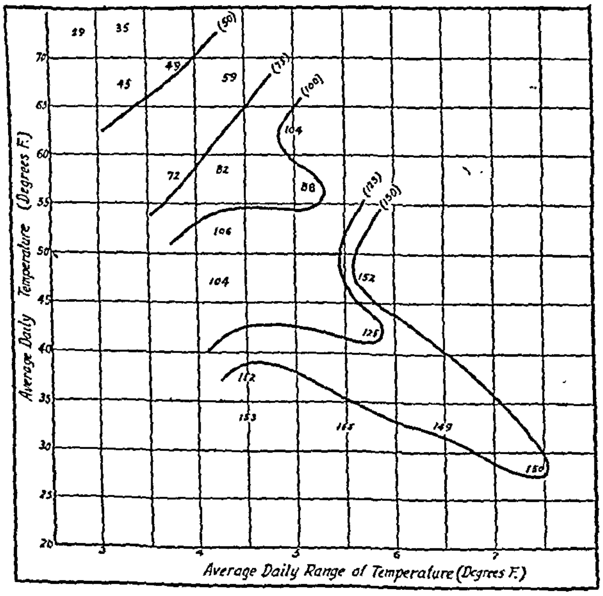

Chart 8.—Relation of daily temperature and daily range of temperature to the prevalence of pneumonia at Newark, N. J., 1906-1915. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and daily range of temperature expressed as a percentage of the annual average.

Since temperature per se is the most important variable influencing the occurrence of pneumonia, it was decided to study the incidence of the disease in relation to both temperature and temperature variability. Charts 7 and 8 show the results charted on this basis for New York City and Newark, N. J. It will be noted that here the lines are oblique and in the direction from left to right, indicating an increase in the death rate corresponding with increasing temperature changes. Thus, the 125 line indicates that on days with a temperature of 55 F. and with a variation of 5.5 degrees, the mortality is as great as on colder days

(38 F.) with a variation of 3.9 degrees. This relationship is more clearly shown in the composite of these four curves, shown in Chart 9. Here it will be observed that with the exception of the bottom curve, a straight line sloping upward from left to right is obtained. This means that (with a certain temperature) less favorable conditions are obtained when the temperature variability is great than when it is small. This relationship is also shown by reading the values at the same temperature from left to right (horizontally), and it will be noted that (with the exception of the region from 30 to 35 degrees) the values (percentage mortality) increase. In other words, this relationship means that at 48 F., with a daily temperature variability of 4 degrees, the same number of deaths occur as at 58 F., with a daily temperature variation of 6.5 degrees.

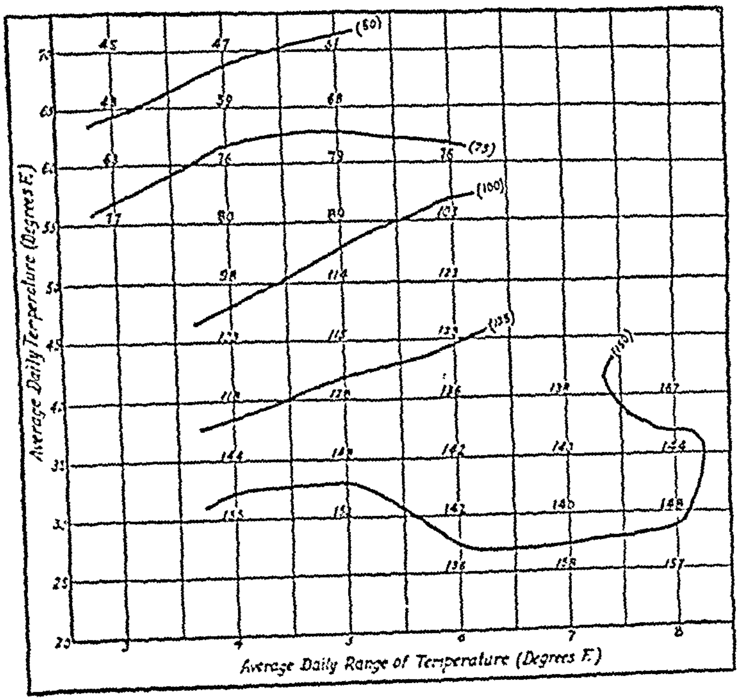

Chart 9.—Relation of daily temperature and daily range of temperature to the prevalence of pneumonia: Composite of New York City, Newark, Boston and Providence. The figures on this graph indicate the incidence of pneumonia that obtains at each specified combination of temperature and daily range of temperature expressed as a percentage of the annual average.

Returning to Charts 7 and 8, it will be seen that the curves are U-shaped. This may mean that a moderate amount of variability is good, while too little or too much variability is bad. This has been found to be true by Huntington, who studied the relation of temperature change to the death rate from all causes. In the case of Newark and New York it will be noted that the curve is distinctly U-shaped at the lower temperatures. That is to say, at this time of the year, when greater fluctuations of temperature occur, wide variations are better borne, possibly because the body becomes better accustomed to cold. However, this point is not conclusively demonstrated by this study, although the curves for New York and Newark are very suggestive.

RELATION TO WIND

I am inclined to believe that Anders overestimated the relationship of wind to the incidence of pneumonia. Table 3, constructed from his data, does not seem to show any such correlation.

That is, February, the month of maximal wind velocity (12 miles an hour), does not show the corresponding largest number of deaths, whereas January, which is the month of maximal deaths, shows a lower wind velocity than February, March or April. In regard to wind direction, Anders believes the assumption to be warrantable that as a rule the direction of the wind (northwest) bears a close relation to the period of maximal mortality from pneumonia. The effect of the northwest wind, according to climatologists, merely lowers the temperature, so that the relation as found by him really corresponds to one of temperature and not to wind direction.

This factor was also studied by me. Beginning with New York City for the years 1901-1915, no definite or distinct curves could be obtained, and it was not deemed advisable to continue the study for the other cities, since New York furnished the largest group of available data.

TABLE 3.—RELATIONSHIP OF WIND TO INCIDENCE OF PNEUMONIA

Month	Wind Velocity per Hr.	Deaths	Month	Wind Velocity per Hr.	Deaths
January	10.8	421	July	9.2	91
February	12.0	372	August	8.1	80
March	11.8	350	September	9.0	83
April	11.6	304	October	10.2	127
May	10.2	224	November	8.3	194
June	9.3	117	December	10.7	286

As a check on this method of studying the relation of meteorological conditions to pneumonia by means of the climograph, it was desired to see whether a disease that is prevalent under conditions different from those influencing the occurrence of pneumonia would also show a characteristic curve. For that purpose diarrhea and enteritis (under 5 years) was selected, since this disease occurs under conditions of high temperature. Chart 10, for New York City, shows that the lowest incidence from this group of diseases occurs when low temperatures prevail; and conversely, the greatest incidence is to be found under conditions of high temperature and humidity—a result that is in conformity with our present views regarding

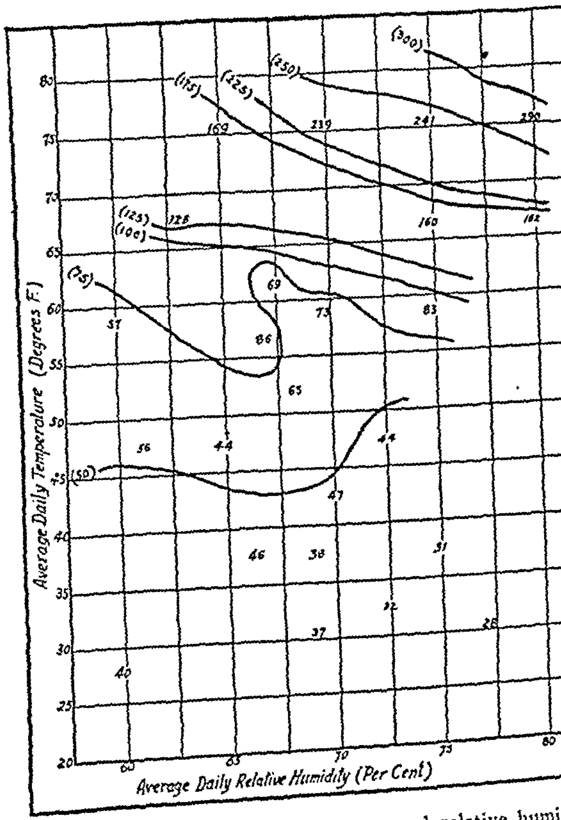

Chart 10.—Relation of daily temperature and relative humidity to the prevalence of diarrhea and enteritis (under 5 years) in New York City, 1905-1916. The figures on this graph indicate the incidence of diarrhea and enteritis that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

the causation of these diseases. It will be noted from this chart that from 65 F. and upward the death rate rises as the relative humidity increases (the percentages being read from left to right).

As a further check on this method I took cancer as a disease that should show no seasonal prevalence, and plotted the deaths in the manner above described, and the result is shown in Chart 11.[9] It will be seen that in this case, as would be expected, the incidence is practically equal under all conditions of temperature and humidity and hence no regular curve can be drawn through these points.[10]

SUMMARY

In studying the death rate of lobar pneumonia in its relation to meteorological conditions, it has been found that:

1. Temperature per se is the most important controlling factor.

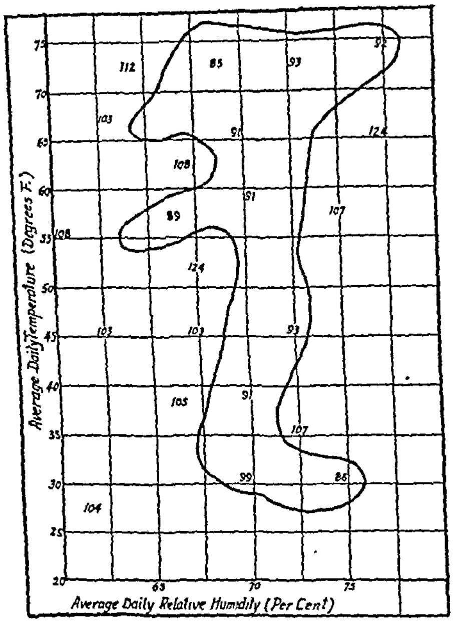

Chart 11.—Relation of daily temperature and relative humidity to the prevalence of cancer at Newark, N. J., 1906-1915. The figures on this graph indicate the incidence of cancer that obtains at each specified combination of temperature and relative humidity expressed as a percentage of the annual average.

2. A low relative humidity is conducive to a high death rate, and a high relative humidity to a low death rate.

3. Increases in the death rate correspond to increasing temperature variations.

---

[9] The curve passes through all points having percentage mortality of 100.

REACTION OF LEUKOCYTES AFTER VACCINATION WITH ARMY TRIPLE TYPHOID LIPOVACCINE *

J. WHEELER SMITH, Jr., M.D.
First Lieutenant, M. C., U. S. Army
WASHINGTON, D. C.

Cournmont and Devic[1] found that injection of typhoid and paratyphoid saline vaccines quickly cause a leukocytosis marked by polynucleosis with neutrophilic myelocytosis. In several cases after the use of an ether-killed vaccine, a mild mononucleosis followed the phase of polynucleosis. After the use of a heat-killed vaccine, mononucleosis following polynucleosis was a rarity. Hallion and Mery,[2] in their study of the modifications of postvaccinal leukocytosis after successive doses of heat-killed T. A. B. vaccine, found that their results agreed with those of Courmont and Devic to the extent that a polynuclear leukocytosis followed the injection of the vaccine which later gave place to mononucleosis. They found, also, that the leukocytic reactions after successive doses became progressively less intense. Mery and Girard[3] found that the polynucleosis following the injection of the heat-killed T. A. B. vaccine is independent of the method of injecting the vaccine. They found that after injection there is a polynuclear increase and then a tendency to mononuclear increase with a leukopenia. Mery and Girard[4] a little later presented the results of their study of the modifications of the leukocytes in the blood of man following vaccination with large doses of a heat-killed T. A. B. vaccine. They observed the same leukocyte changes as after smaller doses, but they were more marked. To sum up the experiences of the French investigators: Vaccination with the various vaccines T. A. B., whether given subcutaneously or intravenously, and whether ether-killed or heat-killed, is followed by a very rapidly appearing polynuclear leukocytosis which reaches its maximum within from four to eight hours and disappears within forty-eight hours. In some cases it is followed by a mild leukopenia marked by a relative mononucleosis.

The present study has been undertaken in an effort to determine the reaction of the white blood cells in individuals vaccinated with the Army triple typhoid lipovaccine.

PLAN OF STUDY

Subjects.—The subjects of the study were eighteen healthy young men who throughout the course of the investigation were student officers at the Army Medical School, Washington, D. C. Several of the subjects were at various times during the study victims of conditions such as laryngitis, pharyngitis, bronchitis, frontal sinusitis, gastro-intestinal derangements of an acute transient nature, and in one instance what appeared to be an attack of renal colic. These departures from the normal exercised very little if any influence on the curves.

Average Normal Figures.—Before the vaccine was administered, leukocyte counts were made on four successive days for the purpose of establishing the normal figures for each individual. These counts were made in the forenoons of July 17, 18, 19 and 20.

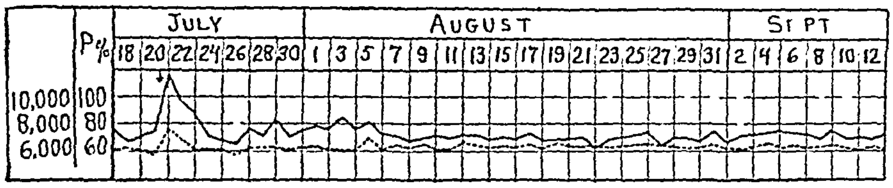
Vaccination.—At 1 p. m., July 20, each of the subjects received 1 c.c. of the lipovaccine prepared at the Army Medical School and containing 0.4 mg. of the dried bacterial substance of each of the organisms *Bacillus typhosus*, *B. paratyphosus* A and *B. paratyphosus* B. Some of the subjects had been vaccinated previously, and some had not. Two of the subjects had had typhoid fever, one six years before and one eight years before. These two men (4 D and 17 U) had never been vaccinated.

Time Relationship of Counts to Meals.—It is very probable that after August 15 the variation in the leukocyte count and in the percentage of polymorphonuclear neutrophils is not dependent on the lipovaccination, but is due entirely to physiologic influences, chief among which is probably the process of digestion. An effort was made to have the subjects report for the counts at the same hour each day; but from the very first this was found to be impracticable because of the nature of the occupation of the subjects. The program of studies at the school varies from day to day, so that the men found it impossible to report at any one hour day after day, but were compelled to seize any opportunity that presented itself to report for the count. It is interesting to note that in the composite table and graphs all the little daily variations have been flattened out.



Composite graphs of the eighteen cases, showing the daily average total leukocyte count (solid line) and percentage of polymorphonuclear neutrophils (broken line). Arrow indicates when vaccine was injected.

METHODS OF WORK

Pipets.—In the beginning a different white blood cell counting pipet was provided for each individual. The pipets were not standardized, so it was considered highly advisable to employ the same pipet for each individual during the course of the study. This was made impossible in three cases by the breakage of pipets. This happened in Cases 1 A, 8 La and 9 Lc. However, it would seem that the substitution of other pipets for those broken in these cases made no great difference in the leukocyte counts.

Manner of Counting Leukocytes.—The technic of counting leukocytes that we employed in this series is that which is usually used. Puncture of the finger tip or, in a few cases, of the lobe of the ear (as the patient preferred) was done with an ordinary spring lancet. The blood was drawn to the 0.5 mark of the pipet, and the diluting fluid, 2 per cent. solution of acetic acid in distilled water, was drawn to the 11 mark. The mixture was thoroughly shaken and in most instances counted within the succeeding hour, being shaken again immediately before counting. The ordinary Thoma hemacytometer with the Zappert-Ewing ruling was employed, and the cells in the four corner squares and in any one of the other squares were counted. The sum of these cells was multiplied by 40 (which is the product of 2, for the full cubic millimeter, and 20, for the dilution). Only one drop from each pipet was counted as a rule, and this was taken after the contents of the pipet had been thoroughly shaken and about one half expelled. Whenever a count appeared to be exceptionally high or unduly low, it was verified by the examination of a second drop.

Manner of Making Differential Counts.—The spreads for the differential counts were made on slides. The slides used were thoroughly cleaned by immersion for twenty-four hours in a sulphuric acid-potassium bichromate mixture. They were then washed in running hot water, immersed in 95 per cent. alcohol and dried out of alcohol.

A drop of blood of the size to give a satisfactory spread was picked up on the end of one slide and then drawn, rather than pushed, along the surface of another slide. The suggestion of Bulloch[5] was adopted in respect to leaving a free edge along the length of the slide. This edge was invariably found to be thin and very rich in well-stained, flattened out leukocytes. The spreads were permitted to dry in the air and were then fixed and stained with Wright's modification of the Romanowsky stain. The differential counts were made with a mechanical stage and an oil immersion lens, 100 leukocytes being counted in each preparation.

COMMENT ON COMPOSITE TABLE AND CHART

The average normal white cell count for the entire series, based on the average of all of the counts for the four days before vaccination, was 7,224.2. This rose on the day after vaccination to 11,758.9; then during a period of five days it fell so that on the eighth day after vaccination it was 6,575.6. Then followed an undulant rise and fall covering a period of thirteen days which reached its high points, July 29 and August 3, in counts of 8,184.4 and 8,331.1, respectively. It terminated, August 8, in a count of 6,844.7. Thereafter the leukocyte count remained at normal.

The average normal leukocyte count, based on the counts for the four days before vaccination, was 7,224.2. For the nineteen days following vaccination, during which time occurred the primary and secondary periods of elevation, the average number of white cells was 7,872.4. Then throughout the rest of the study the average count was 7,122.9. The average normal percentage of polymorphonuclear neutrophils was 60.6. It rose on the day after vaccination to 76.1, but fell so that on the third day after vaccination it was 60.8. It remained at about 63 during the rest of the study, falling below 60 on only one occasion. July 26, concomitant with a leukocyte count of 6,575.6, the percentage was 57.2.

These composite graphs show very plainly the salient features of the leukocyte reaction to this type of vaccination. There appear to be two periods of elevation of the leukocyte count, a primary rise which occurs immediately after vaccination which is followed by a gradual diminution in the white cell count over a period of five days, and a secondary rise, much less in degree than the primary but of very much longer duration. The primary rise is accompanied by a moderate polynucleosis. The depth of the following decline is accompanied by a mild mononucleosis. The secondary rise is unaccompanied by any change in the differential count.

SUMMARY AND CONCLUSIONS

Eighteen healthy young men were inoculated, July 20, 1918, each with 1 c.c. of the Army triple typhoid lipovaccine containing, per cubic centimeter, 0.4 mg. of the dried bacterial substance of each of the organisms *Bacillus typhosus*, *B. paratyphosus* A and *B. paratyphosus* B. For four days prior to vaccination and for fifty-six days after vaccination they were examined as to their total leukocyte and differential counts. The results of this investigation are presented in the form of a composite table and composite graphs. The study of these records makes it apparent that subcutaneous injection of the triple typhoid lipovaccine is succeeded by a rapidly appearing polymorphonuclear neutrophil leukocytosis which gradually disappears during a period of from four to six days and reappears immediately thereafter for a period of from seven to fourteen days. In exceptional cases the initial leukocytosis and the secondary leukocytosis, one or both, are followed by a mild degree of leukopenia with mononucleosis; but in the majority of cases, vaccination with the lipovaccine does not lead to diminution in the number of leukocytes or of the percentage of polymorphonuclear neutrophils, but on the contrary, actually induces a polymorphonuclear neutrophil leukocytosis, of varying degree, over a period of approximately two weeks.

HISTOPATHOLOGY OF SUPERFICIAL BURNS *

H. G. WEISKOTTEN, M.D.

SYRACUSE, N. Y.

The purpose of this paper is to point out the findings at necropsy in fatal cases of extensive superficial burns, and the bearings of these findings on the causative factors in the production of symptoms and death.

Although much has recently been written on the treatment of superficial burns, little has been reported in recent years on the pathology. Divergent views are held as to the cause of the symptoms following extensive superficial burns, and as to the cause of death in the fatal cases. The clinical manifestations have been interpreted by some as indicating shock produced by extreme affection of the nervous system, and by others as indicating profound toxemia.

The results of the experimental work have been rather contradictory and inconclusive. Some of the experimental work points to the existence of a toxin acting in the body after extensive burning of the skin, some to loss of function of the erythrocytes and the production of thrombi as the essential factors in the causation of symptoms and death, while the work of others points to severe affection of the nervous system as the main factor. In general, the results of the experimental work indicate that if toxins are present in the tissues after extensive superficial burns they are complex and have not proved easily demonstrable.

In 1897, Bardeen[1] reported the necropsy findings in five fatal cases. In all of his cases, which were in children, death occurred within a few hours after the burns were received. In all of the cases Bardeen described rather characteristic changes in the lymphoid tissues of the body. These changes consisted in an early edematous swelling of the follicles, followed by necrosis and an accumulation of large, flat, phagocytic endothelial cells. These changes were found to be most marked in the centers of the follicles. He also noted parenchymatous degeneration of the liver and kidneys. He states that the heart muscle was quite normal and that examination of sections from the brain, suprarenal, pancreas, thyroid and thymus revealed nothing of note. As a result of his study of these five cases, Bardeen feels that one of the main causes of death is toxemia caused by alterations in the blood and tissues.

---

* From the Department of Pathology, Syracuse University College of Medicine.

[1] Bardeen, C. R.: A Study of the Visceral Changes in Extensive Superficial Burns, J. Exper. Med. 2: 501, 1897.

It seemed that further study of the tissues at necropsy in uncomplicated fatal cases of superficial burns might disclose other evidences of more or less characteristic lesions resulting from selective action of any poison that might be present. The work of Bardeen suggests that the lesions described were produced by some circulating poison having a selective action on the lymphoid tissues. It would seem that a further study of such cases at necropsy and of cases in which death did not occur as soon after the burning as in Bardeen's series might throw further light on the question.

With this idea in view I have made an anatomic study of ten fatal cases of superficial burns. Of these cases, five were in children and five in adults. The ages varied from 19 months to 60 years. The interval between the time the burns were received and death varied from a few hours up to twenty days. In one case, death occurred within five hours; in three, at the end of one day; in one, at the end of two days; in one, at the end of three days; in one, at the end of four days; in one, at the end of six days; in one, at the end of sixteen days, and in one at the end of twenty days. The burns were produced in a variety of ways, including scalding, actual fire from burning clothes, explosion of a boiler, and burning gasoline.

FINDINGS AT NECROPSY

The necropsy findings in the different cases coincided to such an extent that I shall not give a detailed account of the findings in each case, but shall indicate any differences that occurred in the general description of the findings in the various tissues.

External Examination.—In all cases, large areas of the body surface showed evidences of burns. The degree and extent of the burns varied, most cases presenting areas over which the epithelium had apparently peeled off. In none of the cases was there evidence of charring.

Suprarenals.—Most prominent and characteristic of the necropsy findings were the changes in the suprarenals. The suprarenals were makedly swollen and deep red. There was marked edema of the perisuprarenal fat tissue. On section, the cortex and medulla appeared markedly swollen and showed reddish streaks suggesting congestion of the blood vessels. Certain areas appeared homogeneously deep red, suggesting extensive hemorrhage obliterating the normal markings.

On microscopic examination there was evident marked congestion of the blood vessels with scattered areas of hemorrhage penetrating among the parenchymal cells. There were in the blood vessels in some cases possible evidences of hemolysis and of thrombi, but these were not definite enough to warrant any positive statements. The gland cells were pale staining and much swollen. Many showed apparent hydrops. Necrotic gland cells being invaded by polymorphonuclear and endothelial leukocytes were not infrequent. The lesions in general were more or less comparable to the central necrosis occurring in the liver of the guinea-pig in chloroform poisoning, except that in the suprarenals the process was diffuse.

In the cases of a duration of less than twenty-four hours, the changes were slight as compared with the cases of longer duration; however, even in the five hour case there was present definite congestion and swelling of the glands. In all of the cases of more than twenty-four hours' duration, the changes in the suprarenals were very striking and apparently characteristic. In one case the left suprarenal measured 9 by 3 by 1.5 cm., and weighed 20.5 gm.; the right measured 7 by 4.5 by 2.5 cm., and weighed 25 gm. (the average normal weight being from 4 to 7 gm.). This was the case of a railroad fireman, aged 21, who received extensive superficial burns of the face, forearms, thighs and legs as a result of a boiler explosion, and died three days later. As far as I know, such marked changes in the suprarenals, at least in man, have not been observed in any other condition. About a year ago I published a note[2] describing these changes as occurring in the suprarenals in four fatal cases of superficial burns.

Kolosko,[3] in 1914, described what were apparently similar findings in the suprarenals in a number of fatal cases of extensive superficial burns. He interpreted the findings as representing hemorrhagic infarction of the glands.

Spleen.—Grossly, the spleen did not appear unusual in any of the cases unless it was that the splenic nodules appeared rather prominent in some of the cases. Microscopically, in all of the cases of less than three days' duration there were found rather characteristic lesions in the lymph nodules. Their development could apparently be studied in the lesions of different durations. Early there occurred apparent edema of the germinal centers of the lymph nodules. There was apparent necrosis of the cells of the germinal centers evidenced by karyorrhexis. Endothelial leukocytes accumulated in the centers of the nodules. These endothelial leukocytes were phagocytic for the necrotic cells and for the lymphoid cells of the nodules. Occasionally some of the endothelial leukocytes fused to form foreign-body giant cells. In many instances this process continued until the lymph nodule was represented by a large central area filled with phagocytic endothelial leukocytes surrounded by a narrow ring of lymphoid cells. These lesions apparently developed very soon after the burns were received, and were evident in all of the cases of less than three days' duration. In the cases of more than three days' duration, there were areas corresponding in distribution to the lesions described in the earlier cases. These areas were relatively homogeneous and eosin staining with occasional vesicular nuclei. At the periphery of some of these were seen occasional cells resembling the endothelial leukocytes seen in the earlier lesions. These appearances suggest that the areas represent the earlier lesions in process of hyaline degeneration and resolution or repair. The spleens in some cases showed in the blood sinuses what might be evidences of thrombi and of hemolysis; but these were not definite enough to warrant any positive statements.

---

[2] Weiskotten, H. G.: Fatal Superficial Burns and the Suprarenals, J. A. M. A. **69**: 776 (Sept. 8) 1917.

[3] Kolosko: Ueber Befunde an der Nebenniere bei Verbrennungstod, Vrtljschr. f. gerichtl. Med. 1, Supp. **47**: 217, 1914.

Lymph Nodes.—The changes in the lymph nodes correspond in all cases with changes described in the lymph nodules of the spleen. These changes were found in the cervical, bronchial and mesenteric lymph nodes. The involvement of the lymph nodes, irrespective of their location and involvement of germinal centers of the nodules, suggests that the changes are due to the presence of a poison in the circulating blood and not to a poison brought to the nodes by way of the lymph stream.

Heart.—In two cases, areas of hemorrhage were found beneath the endocardium lining the left ventricle. No other gross changes were evident in the heart. Microscopically there was evidence of injury to the muscle fibers. In four cases (one day, one day, two days and three days), there was evident hyaline degeneration of the muscle fibers. In one case (three days) there was definite necrosis of some of the fibers, with a reaction represented by an accumulation of polymorphonuclear and endothelial leukocytes. These lesions are apparently entirely comparable to the lesions occurring in the heart in diphtheria, scarlet fever and other severe toxemias.

Kidney.—No constant changes were observed macroscopically. Microscopically, in four of the cases (one day, one day, one day and two days), fibrin thrombi were present in the capillaries of the glomerular tufts. The fibrin occurred in threads and network and in solid masses more or less completely occluding the vessels. According to Mallory,[4] this type of lesion "can be produced experimentally in animals by the injection of diphtheria toxin."

Gastro-Intestinal Tract.—Four of the five cases of more than two days' duration showed punctate areas of hemorrhage into the mucous membrane of the stomach or intestine. In the case of twenty days' duration, punctate ulcers were evident in the mucous membrane of the stomach and duodenum. The lymphoid tissue of the intestine showed changes comparable to those found in the spleen and lymph nodes.

Liver.—No constant changes were evident in the liver on gross examination. Microscopically, in two cases, foci of necrosis of liver cells were evident.

Pericardial Cavity.—In the two-day case a few punctate areas of hemorrhage were evident beneath the epicardium.

Lungs.—In two cases there was found moderate congestion of the lungs, and in two cases moderate edema. Otherwise the lungs showed nothing unusual.

Peritoneal Cavity.—In three of the six cases in which death occurred within three days, there was definite congestion of the abdominal vessels. Otherwise the results of the examination of the peritoneal cavity were negative.

Other Tissues.—Of the other tissues, the pleural cavities were examined in all cases; the pancreas was examined in four cases; the thymus in five cases, and the brain in one case. Such examination showed no changes that would warrant any statement in regard to them in connection with this class of cases.

COMMENT

From these necropsy findings it is evident that there was present in these fatal cases of superficial burns a definite pathologic condition. In addition to the lesions described by Bardeen, there occurred definite and rather characteristic lesions in the suprarenals, heart muscle and kidneys. The lesions found in the lymphatic tissue and in the suprarenals are especially striking. The lesions found in the lymphatic tissues are apparently identical with those occurring in fatal cases of diphtheria and with those produced experimentally in animals by the injection of diphtheria toxin and certain other organic poisons. The changes found in the suprarenals are apparently identical with the changes occurring in the suprarenals of guinea-pigs dying several days after the injection of diphtheria toxin and like, but much more marked than those found in the suprarenals of man in fatal cases of diphtheria. The changes found in the heart muscle are also similar to those occurring in cases of diphtheria and other severe toxemias and as far as I know occur in no other conditions. The changes occurring in the liver, kidneys and intestine, although not so striking, are similar to those occurring in severe infections and toxemias. It would seem that the foregoing pathologic conditions can be explained only by the presence of a poison, circulating in the blood stream, and having more or less specific action on certain of the cells of the body. The similarity of the lesions to those occurring in diphtheria suggests that the poison is somewhat similar to diphtheria toxin, at least in its action on the cells of the body. The question as to the source of the poison in this class of cases can be determined only by further experimental work. Whether or not such experimental work will demonstrate a toxin for which an antitoxin can be produced is an important question.

The occurrence of the lesions described above in the cases in which death occurred within a relatively short time after the burns were received, and the greater severity of the lesions in these cases, indicate that they were due to the burns and not to any undiscovered complications following the burning. In connection with this matter it may be pointed out that the lesions are progressive for a relatively short period. For example, as was pointed out above, retrogression of the lesions of the lymphoid tissues begins at the end of three days, and there is no evidence of progression after this period. The same is true of the other lesions described. This suggests that the production of the poison occurs only within the first three days.

Although evidences of capillary thrombi were found in a few instances, it is obvious that the lesions found could not have resulted from the formation of such thrombi. I will not attempt to discuss the part played by so-called "shock" in this class of cases. Suffice it to say that all of the lesions found in this series of cases suggest the presence of a more or less specific circulating poison as an important factor in the production of symptoms and death.

CONCLUSIONS

1. In ten fatal cases of uncomplicated superficial burns, more or less characteristic lesions were found in the suprarenals, lymphatic tissues, heart muscle and kidneys.

2. These lesions, together with those found in the other tissues examined, indicate the presence in this class of cases of a more or less specific poison in the circulating blood.

DRUG ADDICTION

W. A. BLOEDORN, A.M., M.D.
Lieutenant Commander, M. C., U. S. Navy
WASHINGTON, D. C.

The subject of drug addiction has come to occupy a place of considerable importance, not only in civil life but in the military and naval service as well, and constant efforts are being made to reclaim these derelicts and to prevent the spread of the habit.

In this campaign, the importance of an early and positive diagnosis of drug addiction cannot be overestimated. The addict is regarded, and rightly, as being untrustworthy, unreliable and as a particularly dangerous person to engage in any hazardous occupation. His participation in any naval or military undertaking would expose others as well as himself to the possibility of serious consequences.

From the standpoint of the prophylaxis of drug addiction, the addict himself is responsible in many cases for enlisting new recruits. This tendency to spread the habit is believed to be more prevalent than is generally recognized. In some cases it takes the form of active work in encouraging the use of drugs. There are two reasons for this activity: first, the financial gain derived from bringing in new recruits and selling them the drug, and second, the desire on the part of many addicts for company. The majority of addicts have friends or acquaintances who themselves take the drug. Many of them state that they patronize so-called "clubs" where they indulge in their favorite drug. Investigation of these places often reveals merely a room, badly furnished and ill kept, where the habitués may drop in at odd times of the day or night and relieve themselves by taking a "jab," a "sniff" or a "smoke." These places serve to keep the knowledge of drug addiction from their employers and in many instances from even their immediate family. They also allow the addict quietly to sleep off the effects of a large dose, which he may have felt he needed, without being disturbed.

A large percentage of addicts begin the use of drugs while still minors, and it is during this susceptible period of youth that contact with drug habitués is particularly dangerous. A drug addict should be regarded as a focus of infection who through contact with susceptible individuals serves to spread the habit. The average person is unable to secure drugs on his own initiative, but once his circle of acquaintances enlarges so as to include some member of this large army of noneffectives, he finds habit-forming drugs within easy reach as long as he can produce the price. The addict finds that he does well to cooperate with the distributor, and almost never will give evidence or information that discloses the source of supply. As he becomes more confirmed in the use of the drug, he realizes his dependence more and more; and particularly after running short a time or two and experiencing the pangs of sudden withdrawal of the drug, his chief aim in life comes to be the having on hand of a sufficient supply. Many of these addicts will hoard the drug and keep a supply laid away against the time when they may find it hard to procure. It is not uncommon to find the addict penniless and without sufficient clothing, food or shelter, but still clinging to his reserve drug supply, which represents to him the only means of escape from his mental and physical suffering. He pawns his own effects and those of his family, not excepting the kitchen stove, the family clock and his wife's wedding ring. Having exhausted all these resources, he begins to look outside of his own family and to pawn the effects of other people. When reduced to this state he becomes particularly dangerous to society, and will stop at nothing to secure funds with which to purchase the drug for his relief.

DIAGNOSIS

The early diagnosis of addiction will serve in great measure to curtail many of the evils of confirmed addiction and limit the spread of the scourge.

It is an almost certain rule that the drug habitué will endeavor to conceal the fact of his addiction. The instinct of self preservation prompts him to guard his secret carefully. He realizes that his employer would no doubt discharge him at once. His difficulties in procuring the drug would become greatly increased, once it became known that he was an addict. Furthermore, the fear of the law in most cases would prompt him to cover his trail by every conceivable means. In the majority of instances he realizes his own unfitness, and also that his survival depends on concealing the fact of his unfitness.

At first glance it might appear that all these efforts on his part would be useless, that his failing would be fairly easy to discover, and that the ravages caused by his addiction would be discernible to even the layman. The average person, when speaking of drug addiction, has a mental picture, possibly inspired by some stage impersonation he has seen, of an individual more or less emaciated, with sunken cheeks, sallow complexion, and marks of the needle on the arms and body, who nervously starts at the slightest sound and constantly feels himself as if to establish his own identity, who has a habit of sniffing up his nostrils, and who always carries a hypodermic syringe and the necessary ammunition in his coat pocket. While this picture may represent the habitué in some respects, particularly in the late stages of his addiction, it fails absolutely to identify the great army of drug addicts that exists in this country.

The majority of our institutions to which drug addicts are admitted and cared for are not called on to establish the fact of drug addiction. In the patients turned over to them as a rule this fact has been definitely established. In the great majority of cases the diagnosis is arrived at in one of two ways. Either the victim voluntarily seeks relief from the drug, the expense of which has become a serious burden for him, or he is caught with the drug in his possession or in the act of administering it to himself.

As a matter of fact, the diagnosis of drug addiction, contrary to the generally accepted belief, is one of the most difficult problems the physician has to meet. In many instances the habitué indulges in drugs for several years without even his family or associates being aware of the fact. If he is careful as to dosage and the time and place of taking the drug, he may proceed for years and get along fairly well. In examining drug addicts at Bellevue Hospital, this fact was frequently brought out strongly. In one case the addict, after having taken heroin for two years, married, and it was not till a year and a half later that his wife discovered he was a drug addict. He stated that he never took the drug at home but went to one of the so-called "clubs" for regular doses. On one occasion he carelessly took a larger dose than usual, and returning home, was found asleep in a narcotized condition.

In another case, a chauffeur, employed by a physician, took heroin for six months and had no trouble. Finally, he took a larger dose than usual, and while driving the car became sleepy; after he had been roused several times, his condition became evident.

A third case that illustrates this point was that of a sailor who took morphin for more than a year aboard ship and was not suspected. His supply evidently came to him diluted with lactose, as is frequently the case. Getting a fresh supply one day that was not diluted he promptly developed symptoms of acute morphinism and was discovered.

These cases serve to illustrate the fact that drug addicts who are careful to regulate their dosage may pursue their usual occupation for years without being discovered. To establish the diagnosis in such cases, observation over a period of time is necessary. If the addicts are carefully observed, they will almost invariably show signs that lead to a positive diagnosis.

There are two periods in the daily routine of the addict that lead to discovery if unduly prolonged. The first period is ushered in by a feeling of slight nervousness or uneasiness which warns him that it is about time for another dose. If this period is prolonged, he begins to suffer more or less acutely, and cramps and muscular pains become prominent and he has the usual symptoms of sudden withdrawal of the drug. Under usual routine he never gets to this stage, as his equilibrium is reestablished by the drug. But if for any reason the supply is not forthcoming or is delayed, his predicament will usually become noticeable. The second period, during which the diagnosis is much easier, is shortly after the drug is administered and its effect is taking place.

If the addict does not measure his dose carefully, he runs the risk of getting an overdose, which frequently leads to his discovery. He becomes drowsy and may even be found sound asleep at some unusual hour, when his narcotized condition becomes apparent to his employer or to his family. These two periods will occur in the life of every addict to a greater or less degree, depending on the skill with which he regulates the use of the drug, and will tend to become more frequent, the longer he indulges. It is during one of these periods that his condition is usually discovered. He may show no marks of a needle and may stand a most rigid examination without being detected; but when kept under observation over a period of time, he will usually show unmistakable signs.

The early diagnosis of these cases and the placing of the patients under treatment is of the greatest importance to civil communities as well as to the military and naval forces of the country.

IMPORTANCE OF PREVENTION

It is coming to be recognized more or less generally that the solution of the drug addiction evil does not rest on any particular specific or cure. In fact, there is no specific for the condition. It is a comparatively simple matter to get the patient to the stage at which he is taking no more drugs, but it is a much more difficult problem to keep him from backsliding. Our great effort should be along the lines of preventive medicine, and it is here that the early diagnosis of addiction again becomes important.

It appears to be impossible to legislate drug addiction out of existence as long as the drugs themselves exist and are available. The most stringent laws that legislators have been able to enact have failed in great measure to reduce this availability. The addict better than any one else is familiar with the process of obtaining the drug. After passing through an institution for the cure of addiction he comes out with this knowledge still in his possession. If he should meet with reverses or suddenly be called on to face a trying situation, it is only natural that he should seek an outlet by a return to the drug. If the drug were not available, it does not follow that he would seek no other avenue of escape. In fact, if he feels himself unable to face the situation squarely there are several routes that he might take under these circumstances. But these avenues of escape are gradually being closed, and in most cases failure to obtain the drug after having passed through an institution for relief of the habit, and after going for some time without it, would not result in serious consequences.

DRUGS USED BY ADDICTS

Heroin appears to be the drug most easily obtained at present; as a result, the great majority of addicts are heroin users. Also, heroin admits of easy adulteration, requires no apparatus to take, and can be readily distributed. While heroin occupies a place of some importance in the equipment of the physician, it is by no means indispensable, and it could be discarded entirely without serious results.

Cocain and morphin are used by only a small percentage of addicts. The effects of cocain are rather violent, and the addict will usually state that he lost no time in shifting to heroin as soon as he could get it. He realizes that cocain is a much more dangerous drug and requires much greater care in dosage. Its effects are more frequently noticeable, and he is more liable to discovery following its use.

Morphin from the standpoint of the addict is much more desirable than cocain. It is not apt to produce the violent reactions frequently seen after a slight overdose of cocain, and the mental effect appears to be better.

However, the ideal drug for the addict seems to be heroin, and we would do well to pay particular attention to this narcotic. It does not follow that if the manufacture of this drug were stopped entirely we should have the majority of addicts under control; but we should have greatly decreased the availability of habit-forming drugs and should have removed one of the worst offenders among the narcotics.

Opium and its derivatives, ever since their action was known to man, have been the great narcotics on which the individual who feels himself inadequate to face life squarely has rested and drifted with the tide. If we dispose of heroin, it is probably from among these derivatives that substitutes will be sought.

Present Requirements of Physical Education.—We dare not be satisfied with the products of the physical education of yesterday. The value of that physical education has been grimly measured and mercilessly tested since we entered this great war. If you accept the standards of our first draft, you must admit that a rejection of 30 or 40 per cent. of our young men because they were physically unfit for military service would seem to show that our physical education has been only 60 or 70 per cent. effective.—Thomas A. Storey, M.D., State Legislation for Physical Training.

RATIONAL DRUG THERAPY *

JACOB DINER, M.D.
Professor of Pharmacology, Materia Medica and Therapeutics, Fordham University School of Medicine
NEW YORK

The administration of drugs for remedial purposes should be based on a thorough knowledge of physiology, pathology and the principal physiologic actions, as well as the more important secondary actions of the drugs to be administered. The physician should always bear in mind that drugs do not cure. They may be made valuable adjuncts in our endeavor to restore normal function in an abnormally functioning organ.

In administering drugs, one should also bear in mind that the taking of medicine should not be made a punishment or a disagreeable task to the patient, and therefore it is the duty of the prescriber to administer the medicinal agent in as palatable a form as possible. Furthermore, it often happens that the desired physiologic reaction is not obtained from a given drug because of improper mode of administration, or because of failure to select from a given group of drugs the particular drug best indicated in a given case. To illustrate this, I shall take up a few groups of drugs and endeavor to show how selection may be made from the different drugs of the same group in given cases.

SOPORIFICS

In the group of soporifics we find in most textbooks chloral, its derivatives and compounds, the opium series (opium, morphin, codein, ethylmorphin hydrochlorid, heroin, etc.), and the bromids.

Let us now consider the principal action and principal secondary action of each.

The chloral group depresses the central nervous system and, eventually, completely paralyzes it. It has no specific effect on pain sensation, but it does depress the reflexes of the spinal cord, and affects last of all the medulla oblongata, and therefore practically does not depress the respiratory center to any extent. It becomes at once evident that its administration as a hypnotic in a case of insomnia due to pain would be contraindicated, while, on the other hand, it is eminently the remedy of choice in cases of insomnia due to nervous excitation, especially when such excitation is of spinal or reflex origin.

When we bear in mind, furthermore, that chloral is irritating to skin and mucous membranes, it follows logically that it should be administered in high dilution and preferably in combination with some bland substance, so that we would prescribe our chloral hydrate in combination with glycerin or mucilage of acacia and with plenty of water.

Opium and its derivatives, on the other hand, have a pronounced selective action on pain sensation and on respiration, markedly reducing both in doses too small to affect general consciousness. This is especially true of its principal alkaloid, morphin. Therefore, opium and its alkaloids are indicated as analgesics rather than as hypnotics, especially when the rate of respiration is above normal. The possibility of morphin addiction should, of course, be borne in mind.

Bromids act directly as depressants on the central nervous system, reduce the reflexes and impair the passage of impulses from the sensory to the motor cells. Therefore, in a case of sleeplessness due to a moderate degree of excitation, bromids would be indicated. But we must remember that (1) a certain degree of concentration of bromids in the circulating blood and in the tissues is required; (2) bromids are fairly rapidly eliminated, especially in the presence of chlorids; (3) bromids, like all halogen derivatives, are irritating to mucous membranes in concentrated solution, and (4) last, but not least, they have a rather disagreeable taste. Therefore, the administration of the bromids should begin some time before the desired effect is to be obtained, and frequent small doses will bring about greater physiologic response than a single large dose. When a concentration of bromids is to be maintained in the blood and tissues for some time, as in the treatment of epilepsy, the patient should be kept on a practically salt-free diet. The bromids should be administered in high dilution to prevent gastric irritation, and the taste may be corrected by the addition of acid fruit syrups or by a combination of a small amount of citric acid with simple syrup.

STIMULANTS

Turning our attention to the stimulants, we find again a number of drugs or group of drugs, each of which has its special indication. For instance, nux vomica and especially its principal alkaloid, strychnin, has selective action on the spinal cord, and its application is therefore indicated in conditions in which the ordinary normal stimuli fail to bring about the corresponding muscular response, whether of striped or unstriped muscles, generally referred to as lack of tonus.

The caffein group of stimulants must be divided into two subdivisions: caffein and its salts acting on the central nervous system as well as on the kidneys, while theobromin has but little effect on the central nervous system. Caffein produces restlessness to the point of insomnia and mental confusion, has but little effect on the circulation, and quickens the rate of respiration while at the same time decreasing its amplitude. It becomes at once apparent that in such cases as we saw in the recent epidemic of influenza, associated with or followed by lobar and lobular pneumonia, with increased rate of pulse and respiration, together with mental excitation to the point of delirium, caffein was distinctly contraindicated. If it was given with a view of aiding renal excretion, because of the oliguria found in these cases, it seems to me that the drug of choice should have been theobromin sodium salicylate, or better still, one of the many saline diuretics, such as the citrates and acetates of ammonium, sodium or potassium. On the other hand, caffein would be indicated in cases of mental or psychic depression, and particularly in cases of depression incident to poisoning.

For a similar reason, that is, its accelerating effect on the respiratory rate, atropin was contraindicated in these cases, excepting when it was desired to check secretions, as in impending edema; but its influence on secretion to the extent of lessening perspiration would also have to be considered, and for this reason morphin would probably be preferable because of its selective action in lessening all secretions except those of the sweat glands. Neither would camphor be indicated in the above mentioned cases, because in physiologic doses its effect on heart and respiration is relatively small and in larger doses may cause an acceleration,

---

* Read before the Bronx County Medical Society, Nov. 20, 1918.

especially of the heart rate, rather than a slowing. But the dilating effect of the camphor group on the peripheral blood vessels could well be utilized by external applications of alcoholic menthol solutions.

The group of drugs that stands out as eminently satisfactory in the conditions mentioned is the digitalis group. The principal two members deserving prime consideration are digitalis, its preparations and active principles, and those of strophanthus. One must bear in mind that absorption of digitalis from the gastro-intestinal tract is slow, and that, even after it reaches the blood, the effect on the heart is markedly delayed. But such action, once begun, is sustained for some time, while the opposite is the case with strophanthus, in which cardiac reaction is more prompt but not long sustained. Therefore, for emergency cardiac stimulation the strophanthus group is indicated, while the digitalis group has its place when conditions permit delay of reaction until the cumulative but sustained effect is reached.

IMPROPER ADMINISTRATION OF DRUGS

As an illustration of improper mode of administration of drugs, let me cite two examples. Magnesium sulphate is well known to all of us as an efficient saline laxative; but few physicians remember that the rapidity of its action is in inverse proportion to the concentration. The greater the concentration, the slower is the action, and, inversely, the less the concentration the more prompt the response. Therefore, if we wish to obtain prompt results from a dose of Epsom salt it should be administered with a large amount of water, while in cases in which delayed action is required or absorption of fluids from the tissue is aimed at, the less water used for conveying it, the better the results. This drug, too, may be made palatable by the addition of a little citric acid and sugar or by the admixture of some orange juice to the water used as solvent.

Another example of improper drug administration is furnished by the usual methods of prescribing digestants. We know that carbohydrate digestion, initiated in the mouth, is continued for some time in the cardiac end of the stomach until the gastric secretion attains a certain degree of acidity. Then, about thirty minutes after food reaches the stomach, the pepsin and rennin in the presence of the hydrochloric acid begin their enzymic action. It becomes at once apparent that the administration of pepsin and hydrochloric acid immediately after eating will inhibit any carbohydrate digestion in the stomach. Yet most prescribers direct pepsin to be taken immediately after eating. Logically they should not be taken until from thirty to forty-five minutes after eating. In the case of pancreatin medication even greater sins are committed. This collection of enzymes is normally active in the small intestine, in an alkaline medium, and begins its work in from two to three hours after eating.

Pancreatin belongs to the proteins and is subject to all the chemical laws affecting them. If introduced into the stomach at the height of its activity in a form accessible to the action of the gastric enzymes, it will, at least to a great extent, be digested and will not pass into, nor be available for its own enzymic function, in the small intestine. For these reasons pancreatin should be administered in a form in which it will not readily be acted on by the gastric secretions, that is, it should be prescribed in an enteric coated capsule, and should be introduced toward the end of the normal period of gastric digestion, which would be about two to three hours after meals. And it would surely be a mistake to administer pepsin, rennin, diastase, pancreatin and hydrochloric acid in one solution. Another thing to be remembered in connection with enzymes is the fact that alcohol inhibits their action, and therefore the administration of these in the form of elixirs or wines appears illogical.

In the time allotted for a paper which, I fear, I have more than exhausted, one is necessarily compelled to limit oneself to broad outlines, rather than to indulge in detailed minutiae. I have therefore endeavored merely to point out the possibilities of careful analysis of drug action within the realm and reach of the general practitioner of medicine.

INFLUENZA AT THE UNITED STATES NAVAL HOSPITAL, LEAGUE ISLAND, PA.

FRANCIS J. DEVER, M.D. (Philadelphia)
RUSSELL S. BOLES, M.D. (Philadelphia)
and
EUGENE A. CASE, M.D. (Lansdowne, Pa.)
Lieutenants, M. C., U. S. N. R. F.
LEAGUE ISLAND, PA.

Influenza first made its appearance in epidemic form at the U. S. Naval Hospital, League Island, Pa., Sept. 12, 1918, on which day sixty-six patients were admitted from the receiving ship extension barracks. The epidemic continued in unabated form until September 17, when the crisis was reached.

Our clinical observations were made on 600 cases of influenza of which 168 patients developed pneumonia; of the latter, forty-eight died. The disease spread more rapidly among men in barracks than among those living in tents.

In general, the prognosis in uncomplicated cases of influenza is good as to life. Several instances of acute pulmonary tuberculosis have been observed following an attack of influenza, and it is very probable that latent tuberculosis lesions are converted into active foci by the influenza infection. Influenza occurring in patients with chronic diseases, such as nephritis, is a very serious matter.

TREATMENT

No specific treatment has been found to date. A more or less routine treatment adapted to the individual requirements was carried out in this hospital with uniformly good results. On admission the patient was put to bed and magnesium sulphate ordered. Ten grains of pulvis ipecacuanhae et opii (Dover's powder), with a glass of hot unsweetened lemonade, tea or milk were then administered. A mustard plaster usually relieved the pains or oppression in the chest. If not, a small dose of codein or morphin was given. In all cases the coal tar products were withheld on account of the prostration already present. When the general muscular pains and headaches were quite severe, acetylsalicylic acid in 5 grain doses was given with benefit. Quinin was used with caution because of the possibility of middle ear disease. In practically all cases one-half ounce of liquor potassii citratis was given every three hours until the acute stage was passed. Stimulation, usually consisting of tincture of nux vomica or strychnin, caffein and whisky were frequently employed. Whisky was not given when nausea or other gastro-intestinal symptoms were present. Water in large quantities was insisted on. The bowels were kept open daily. Food was prescribed according to the patient's appetite, regardless of fever. Certainly no good can come in starving patients so desperately in need of the proper kind of nourishment.

The treatment of pneumonia was entirely symptomatic. If Type I pneumococci could be isolated, the specific serum was employed. Glucose in 15 per cent. solution, with or without sodium bicarbonate given by rectum by the drop method is an aid in combating severe toxemia. Venesection was resorted to in a number of cases with absolutely no benefit.

USE OF VACCINES

After the nature of a drowning person grasping at a straw, a stock influenza vaccine was used as a preventive in fifty individual cases and as a curative agent in fifty other uncomplicated cases.

TABLE 1.—FORMULA OF THE VACCINE

	Per C.c.
Influenza bacillus	200,000.000
Pneumococcus	100,000 000
Streptococcus	100,000,000
Staphylococcus pyogenes-aureus	200,000 000
Staphylococcus pyogenes-albus	200 000 000
Micrococcus catarrhalis	200,000,000

As a preventive it was given every forty-eight hours for four doses. The first injection was 0.3 c.c., the second 0.6 c.c., and the third and fourth 1 c.c. In no case was there any severe reaction, and none of the individuals contracted the disease. Most of them were hospital apprentices working in wards for from twelve to fifteen hours a day. Of course, other safeguards were insisted on, such as wearing a mask continually while in the ward and observing the strictest cleanliness of the hands and body. Some few, however, who wore a mask and were not injected became victims of the infection. Let it be said here that the careful and consistent wearing of a properly fitting mask can be expected to afford a reasonably certain protection against the disease.

In the fifty uncomplicated cases treated with vaccine, none of the patients developed pneumonia, and but one developed pleuritis. After a stubborn and prolonged resistance, the pneumonia patients succumbed. The course of the disease in the others, with few exceptions, was definitely shortened, and prostration seemed less severe. The patients apparently not benefited were those admitted from four to seven days after the onset of their illness. These were out of all proportion to the number of pneumonias that developed and the severity of the infection of the control cases. The effects were always more striking, the earlier the vaccine was administered.

The number of patients treated with vaccines and the number immunized with it is entirely too small to allow of any certain deductions; but so far as no untoward results accompany their use, it would seem unquestionably safe and even advisable to recommend their employment.

LABORATORY STUDIES

The bacteriologic studies of this epidemic made thus far have not been conclusive, though most of the observers have demonstrated *B. influenzae* in a considerable proportion of their cases.

Little, Garofalo and Williams[1] failed to find *B. influenzae*, but did find a gram-negative diplococcus in all their cases.

Gotch and Whittingham[2] have found *B. influenzae* in 8 per cent. by cultural methods and in 62 per cent. in stained smears from the sputum, and attributed the infection to a gram-negative coccus, "perhaps in association with the influenza bacillus."

Averill, Young and Griffiths[3] were able to cultivate the Pfeiffer bacillus from the sputum.

Matthews,[4] using a trypsinized blood agar medium, found this organism in all of twelve cases studied. His cultures were made from the nasopharynx by means of the test tube.

Martin[5] found the influenza bacillus both in smears and in cultures and believes the epidemic to be true influenza.

Krumbhaar[6] takes issue with Little, Garofalo and Williams, finding *B. influenzae* in three fourths of a small group of cases.

Keegan,[7] in this country, had rather unsatisfactory results from sputum cultures and mouse inoculations, but found *B. influenzae* in some of his cases. In cultures from the lungs, however, in twenty-three cases, he was able to isolate the organism in 82.6 per cent., 31.6 per cent. being pure cultures.

Barnett[8] made several unsuccessful attempts to isolate the organism from the sputum and nasopharyngeal smears at a naval base in Scotland.

It is well to repeat, however, what has been pointed out before,[9] that the causative organism was not discovered during the epidemic of 1889, but in 1892, when Pfeiffer demonstrated the bacillus that bears his name.

In the studies conducted at the League Island Hospital, the medium used was unlaked human or rabbit blood agar titrated to plus 0.5 and citrated bouillon, containing blood and having the same reaction.

One hundred and five cultures were made from the sputum, thirty-four from the nasopharynx, eleven from the laryngeal region and eleven from the eye. In only four cases was *B. influenzae* isolated in pure culture, though in some twenty cases an organism similar in morphology and staining characteristics was present, all obtained from the sputum. Stained smears of sputum showed an organism resembling the Pfeiffer bacillus in a good percentage of the cases studied. Numerous other organisms were found, the most important being the pneumococcus in the majority of the cultures, streptococci, the nonhemolytic strain predominating, *Micrococcus catarrhalis* and staphylococcus.

The presence of these organisms, especially the pneumococcus and streptococcus, while of no very great significance, is interesting in view of the very common complication of pneumonia.

Blood cultures were negative in all but one of twenty-six cases. In this instance, a case of pneumonia in which the patient was moribund at the time, a Type

IV pneumococcus was isolated. The blood was planted in agar and citrated bouillon and cultivated under both aerobic and anaerobic conditions. The results of this study were somewhat disappointing so far as the demonstration bacteriologically of *B. influenzae* as the etiologic factor in the epidemic at this station was concerned. This may have been due to unfamiliarity with the organism and inappropriate culture mediums, though in cases in which positive growths were obtained, the organism was not especially difficult to find and it grew readily on the medium.

PNEUMONIA

Forty-two cases of pneumonia were studied by the Avery method for type determination. In twelve specimens of sputum the results were unsatisfactory, the bouillon cultures showing streptococci, gram-negative bacilli similar to the influenza bacillus, both in association with other organisms, and few, if any, pneumococci.

TABLE 2.—TYPE DETERMINATION BY AVERY METHOD

	Number	Per Cent.
Type I	7	16⅔
Type II	7	16⅔
Type III	5	12
Type IV	11	26
Unsatisfactory	12	28

In one fatal case both a Type II and a Type III pneumococcus was found.

Tables 3 and 4 give the results of the leukocyte and differential counts in uncomplicated influenza and in influenza complicated by pneumonia and pleurisy.

From the tables it will be seen that in uncomplicated influenza the tendency is toward leukopenia, this being well marked in some cases. In the pneumonias complicating influenza, leukocytosis was present in the majority of instances.

TABLE 3.—BLOOD COUNTS IN INFLUENZA

Case	Number of Leukocytes	Polymorphonuclears, per Cent.	Small Mononuclears, per Cent.	Large Mononuclears, per Cent.	Eosinophils, per Cent.
1	6,000	75	20	5	..
2	16,800	85	12	3	..
3	8,000	83	9	8	..
4	8,000	54	48	8	..
5	6,500	78	19	3	..
6	9,000	78	20	2	..
7	5,200	35	22	7	..
8	7,800	59	14	26	1
9	8,200	70	25	5	..
10	4,300	65	22	12	1
11	4,550	68	28	4	..
12	9,000	80	15	5	..
13	8,600	46	30	21	3
14	8,000	48	23	2	28
Average	7,782				

Of three pneumonia patients with leukopenia, two recovered and one died. Of four with a normal blood count, one died. Five of those with leukocytosis died. The differential counts had nothing characteristic about them. One patient, showing eosinophils, subsequently developed otitis media and mastoiditis.

URINALYSIS

The urine of 225 patients was examined; 150, or 66 per cent., contained albumin, and eighty-three, or 37 per cent., casts. Pus cells and leukocytes also were quite common. These findings are an index of the effects of the toxemia on the kidneys, producing distinct kidney irritation even to the extent of well marked parenchymatous change. It is well to remember, though, that the cases of those sent to the hospital were, as a rule, more severe than many treated in the various sick bays at this station.

NECROPSIES

Unfortunately we were able to secure but two necropsies, both of patients dying from pneumonia.

CASE 1.—Consolidation of a dark red, glazed, "meaty" appearance involved the dependent third of the lungs with a fibrinous exudate of mild degree on the corresponding pleural surface. The air-containing portions of the lungs were edematous.

The kidneys presented acute parenchymatous nephritis.

The other organs were not changed to any important extent. Cultures from the heart's blood, lungs and spleen yielded a Type IV pneumococcus.

CASE 2.—There was a consolidation in the lower lobe of the left lung, with slight involvement of the pleura. On the right side, in addition to almost complete consolidation of the middle and lower lobe, there was a large area of consolidation in the upper lobe.

The cut surfaces of these consolidations were similar, presenting a mosaic of dark red, glazed areas, grayish red granular ones, others more of the character of gray hepatization, and some showing a softened exudate, suggesting beginning resolution. This, in our opinion, indicates that the lesion was essentially a bronchopneumonia that had by extension become lobar in distribution.

TABLE 4.—BLOOD COUNTS IN INFLUENZA COMPLICATED BY PNEUMONIA AND PLEURISY

Case	Number of Leukocytes	Polymorphonuclears, per Cent.	Small Mononuclears, per Cent.	Large Mononuclears, per Cent.	Eosinophils, per Cent.

31	25,000	93	4	3	..
32	19,400	78	15	7	..
33	14,400	84	12	2	..
34	14,600	85	6	9	..
35	15,400	79	16	5	..
Average	15,906				

On the right side there was also a serofibrinous pleuritis, with extensive fibrinous exudation.

The kidneys were the seat of well marked parenchymatous changes, and the spleen was moderately enlarged.

Cultures from the heart's blood, both lungs, right pleura and spleen yielded a Type IV pneumococcus.

In neither necropsy was the influenza bacillus isolated.

Infant Mortality and Welfare.—The infant mortality rate is considered the most sensitive index we possess to social welfare. It reflects at once conditions which improve or interfere with the normal health or life of the community. As conditions which make for normal family and community life are improved, the infant death rate decreases. When these conditions are disturbed, the rate correspondingly increases. The infant mortality rate, therefore, may be taken as the barometer of the social welfare of the community.—Handbook of Child Hygiene, Kansas State Board of Health.

THE RELATION OF BRONCHOPNEUMONIA TO INFLUENZA

A PRELIMINARY REPORT

By THE CAMP LEWIS PNEUMONIA UNIT[*]
CAMP LEWIS, AMERICAN LAKE, WASH.

The spread of the so-called "Spansh influenza" epidemic in the various cities and military camps during recent months has been the concern of the medical profession and of the laity alike. Current medical literature deals largely with the subject. The death rate from influenza and its complications in the Army cantonments alone probably exceeds that of the American Expeditionary Forces from all other causes.

When the epidemic reached Camp Lewis, we had at the base hospital a well organized pneumonia unit. This unit was composed of assistants and ward surgeons on the medical service, a laboratory personnel with a day and night service, and an efficient roentgen-ray service. No case of pneumonia was reported unless the findings of the ward surgeon were confirmed by the chief of the medical service or an assistant. In all cases of pneumonia or suspected pneumonia, a sputum study, white blood and differential count, blood culture and urine examinations were made as a routine. Each patient was roentgenographed, unless the condition was critical on admission. Postmorten examinations were made in practically every fatal case.

Early in the epidemic we were forcibly struck by the atypical signs of the pneumonia with which we were confronted. The usual signs of pneumonia in young adults were conspicuously absent. Frank consolidation with high temperature was the exception rather than the rule. The onset of the disease was atypical. Most of the patients gave the more or less typical and accepted history and symptoms on which a diagnosis of influenza are based. They complained of generalized muscle and joint pains, headache, slight dryness of the throat, pains beneath the sternum, and usually a dry and unproductive cough. Rarely was there a history of a sudden and definite chill. In only the most severe cases was there a history of rusty or bloody sputum. On admission the temperature in a majority of cases varied from 99 to 101 F.; the pulse was normal or only slightly increased; the respirations, except in the most severe cases, rarely exceeded 28 per minute, and the distress was usually slight.

On physical examination, the findings were not marked. Usually there was found a slight diminution in resonance over one or both lung bases posteriorly. The breath sounds were variable. Bronchial breathing and pectoriloquy were rarely present. In some cases the breathing was harsh or bronchovesicular, accompanied by an increase in fremitus. In other cases the breathing was diminished with a decrease in fremitus. On deep inspiration, in either type of case, a shower of fine moist or crepitant râles was almost invariably heard over the area of diminished resonance.

From these early and indistinct signs, the course rapidly changed. Within from forty-eight to seventy-two hours there was either a marked extension of the process with definite although atypical signs of a diffuse bronchopneumonia, or the temperature had dropped to normal and the lungs showed signs of resolution. In the more severe cases the temperature remained elevated with only slight increase in pulse and respiratory rate for several days. The temperature then fell by lysis to normal. In the fatal cases the process extended to several lobes or all lobes of both lungs. In the most extensive cases, bronchial breathing and pectoriloquy were occasionally noted.

Laboratory study showed a consistently low white blood count, being usually under 10,000 cells per cubic millimeter, with only slight changes in the differential count. Sputum examinations revealed very uniformly Type IV pneumococcus with a nonhemolytic streptococcus. The other types of pneumococcus or the hemolytic streptococcus were rarely found, in contrast to the almost constant incidence of the hemolytic type of streptococcus in the cases of pneumonia in the spring of 1918. Influenza bacilli were found in only a few cases early in the epidemic. Blood cultures in 825 cases were positive in twenty-four, or 2.9 per cent.; of these, twenty cases showed pneumococci, one hemolytic streptococcus, and one nonhemolytic streptococcus.

Postmortem examinations revealed a bronchopneumonia of varying degree, but usually extensive and involving one or both lower lobes, sometimes associated with involvement of other lobes in all combinations. The process was characterized by scattered areas of pneumonic consolidation varying in size, the larger areas resulting from the coalescence of smaller ones. Frequently the entire lobe or lobes would show consolidation, giving the appearance of a lobar pneumonia. The latter type early in the epidemic led us to make a diagnosis clinically of lobar pneumonia, but further study showed that we were dealing with a coalescent bronchopneumonia. In every case coming to postmortem examination, the presence of a pneumonic process was clearly demonstrated.

Throughout the study the use of the roentgen ray has been invaluable. It was possible in many cases to show by this method the extension of a relatively small and indefinite area of haziness at the base of one or both lungs to a complete involvement of all lobes of both lungs. In contrast to this, however, it was possible to show cases presenting similar areas which did not progress but slowly resolved after the return of the temperature to normal. With the large number of cases studied it has been possible to show all gradations of the process. Frequently the roentgenographic findings revealed a rather extensive process which showed only slight signs on physical examination until from twenty-four to forty-eight hours later. On the other hand, cases in which the physical signs were fairly well marked occasionally showed only moderate changes in radiability. These discrepancies have been explained by the situation of the pneumonic process in the lung tissue, confirmed by stereoscopic plates and postmortem examinations.

SUMMARY

The recent epidemic at Camp Lewis was an acute respiratory infection and not an epidemic due to *Bacillus influenzae*. The acute respiratory infection was characterized by atypical physical signs and extreme variation in virulence.

From the large number of cases studied clinically, roentgenologically, bacteriologically and at postmortem, it appears amply demonstrated that the process, whether mild or severe, is etiologically and pathologically the same; that there are all gradations from a slight involvement of the bronchioles with adjacent alveolar infiltration to an extensive involvement of entire lobes simulating lobar pneumonia; and that the cases were mild or severe, depending on the resistance of the individual or variations in the virulence of the organism, rather than the accepted idea that pneumonia complicated one case and not another.

---

[*] The pneumonia unit was composed of: Medical Service: William J. Kerr, Captain, M. C., chief of the service; *Assistants:* Harvey M. Slater, Captain, M. C.; Hugh K. Berkley, Captain, M. C.; T. Homer Coffen, Captain, M. C.; Thomas G. Clement, Captain, M. C. and ward surgeons. Laboratory Service: Kenneth J. Staniford, Major, M. C.; chief of the laboratory service; Marcus C. Terry, Captain, M. C. Roentgen-Ray Laboratory: F. E. Diemer, Captain, M. C., head of roentgen-ray laboratory and staff.

ANTHRAX AT EMBARKATION HOSPITAL, NEWPORT NEWS, VA.

OTIS T. AMORY, M.D. (Virginia)
Captain, M. C., U. S. Army
and
BENJAMIN RAPPAPORT, M.D. (Chicago)
Lieutenant, M. C., U. S. Army
NEWPORT NEWS, VA.

In view of the recent occurrence of anthrax in the various Army camps, an account of the cases observed at the Embarkation Hospital, Newport News, Va., should be of interest:

REPORT OF CASES

Case 1.—*History.*—A soldier, admitted to the hospital, May 25, 1918, with the transfer diagnosis of mumps, had had headache, May 23, and then noticed a small papule on the left cheek. While shaving, he cut the papule, which bled freely. His face started to swell the same afternoon. Headache increased, then the throat began to swell, deglutition was painful, he had nausea and vomiting, and he felt very chilly. There was a nodule on the left cheek the size of a quarter, with a dark cherry eschar, with a well defined, elevated margin. The temperature was 102.6, the pulse 104, and respiration 28. Two hours later the temperature was 103.4. Anthrax bacilli were demonstrated in smears.

Operation.—May 25, the nodule was excised under local anesthesia, the base cauterized with pure phenol (carbolic acid), 5 per cent. phenol injected into the subcuticular tissue around the excised area, and a 95 per cent. alcoholic dressing kept continuously applied. The wound was dressed every twenty-four hours. The base was cauterized with pure phenol until the edema subsided, and then with 5 per cent. phenol until pure granulations developed. After twenty days, repeated culture failed to demonstrate bacilli, when, under local anesthesia, skin grafting was performed. The patient returned to duty, July 4, with the wound healed.

Comment.—After the operation, the swelling increased for thirty-six hours, extending to the supraclavicular glands; there were no kidney complications. The temperature became normal, May 29, with no subsequent rise. Medical treatment was given from a symptomatic standpoint. Aside from the smear, no laboratory work was done in this case.

Case 2.—*History.*—A soldier, admitted, June 6, 1918, with the transfer diagnosis of parotitis, had noticed, two days prior, a papule on the right cheek, which he picked. Swelling began and very rapidly extended down the neck. There was a pustule, the size of a green pea, with a deeply indurated margin, rather blurred and studded with vesicles, and a dark cherry center. The induration was out of proportion to the nodule. There were no marked constitutional symptoms. A smear showed anthrax bacilli. The patient stated that he had been wearing a chinstrap which rubbed this papule. The temperature was 100.2, the pulse 90, and respiration 20. June 8, the temperature was 104.4, the pulse 110, and respiration 26.

Operation.—June 6, under local anesthesia, the nodule with an indurated area the size of a half dollar was excised, with the same after-treatment as in the preceding case. The patient's temperature of 104.4, June 8, gradually receded until it became normal, June 11. Skin grafting was performed, July 5. The patient was returned to duty, August 3, with a very small area remaining unhealed.

Comment.—This was a normal case with rather marked swelling and great reaction following operation. The organisms in this case were obtained in both smear and culture.

Case 3.—*History.*—A soldier, admitted, July 15, 1918, with undetermined diagnosis, had noticed a small papule, July 11, which itched. He scratched it several times that night. Next day, he noticed a small lump (induration). He ached all over as if he had the grip. The lesion itself was not very painful. The swelling increased. July 13, he reported on sick call. He remained in quarters, July 14, and was sent to the hospital. Smear on admission was positive. He says he went on a hike, July 11, and slept that night on some of his equipment, which put a leather strap against his cheek. July 11, he used a new shaving brush.

Findings.—On the right cheek, at the margin of the lower jaw, there was a black eschar about one-half inch in diameter, with an induration about 1½ inches across. The eschar was surrounded by a yellowish border and numerous vesicles and edema involving the neck, chiefly on the right side. The temperature was 102.2, the pulse 120, and respiration 24. July 16, the temperature was 98, the pulse 70, and respiration 20. There was fever for only twelve hours after admission.

Operation.—July 15, excision of the nodules the size of a silver dollar and the usual operative technic were carried out. Edema disappeared after five days. July 20, phenol was discontinued and physiologic sodium chlorid solution used. Edema reappeared; under phenol it again disappeared. August 18, phenol was discontinued and again the edema appeared, to disappear after the use of phenol. September 19, 40 c.c. of antianthrax serum were given subcutaneously with local swelling; September 23, 40 c.c. of antianthrax serum were given, and irritable heart developed. The patient complained severely, but no pathologic condition was produced. The serum was discontinued; local applications were continued; healthy granulations rapidly formed. At present the wound is practically healed.

Comment.—There was a very slight reaction following the operation. This case was a very stubborn one. On administration of anthrax serum, there was a local reaction about the site of the wound. Organisms were obtained from smear, culture, and the following tissues: from inoculated guinea-pig, blood stream, liver, heart, spleen, and site of inoculation. The guinea-pig died within thirty-six hours after inoculation.

Case 4.—A soldier, admitted, Sept. 21, 1918, with the transfer diagnosis undetermined, had noticed a papule, the day before, on the left side of the face; next day there was edema on one side of the face, but very little pain. He reported on sick call and was sent to the hospital. He arrived at this camp, September 19. He slept on a leather seat and had been using a new shaving outfit, but destroyed it before coming to the hospital.

Findings.—Over the angle of the left side of the lower jaw was a black eschar about 2 cm. in diameter, surrounded by a ring of small vesicles of a dirty dark yellow; there was induration about 1 inch across, and immense edema of the left side of the face, neck and the upper third of the chest. On admission, the temperature was 102, the pulse 112, and respiration 20. After operation the temperature rose to 103.2, the pulse 120, and respiration 18.

Operation.—September 21, excision of the nodule the size of a silver dollar, with the usual technic, was carried out. In addition, 40 c.c. of serum were given. September 22, edema increased, closing the left eye and involving the upper half of the chest; there was slight delirium. September 23, the edema was unchecked. The patient had difficulty in swallowing. Forty c.c. of serum were given intravenously, and repeated four hours later; there was no reaction from the serum. September 25, the edema was subsiding. September 28, the edema had about disappeared. The same treatment was continued with subsidence of all symptoms. The wound at present is rapidly granulating.

Comment.—This was the most severe infection, and the only one producing any delirium. In this case infection was not combated until injections of anthrax serum were used, after which there was a general subsidence of symptoms.

SUMMARY

1. The source of infection was not definitely determined. In two cases, cultures of toilet articles, especially shaving brushes, were made, with no growth. Unfortunately the others were destroyed before we could get them. All the patients wore chinstraps of leather. One had slept, using his haversack as a pillow. Another used a leather seat on the train as a bed. None had been around animals of any kind.

2. The operations were performed under local anesthesia, without any attempt to control hemorrhage, as loss of blood from the site of infection was advisable. Cauterization and injection of 5 per cent. phenol into the cellular tissue, followed by continuous alcohol dressings, are indispensable. Skin grafting decreased the period of convalescence by weeks.

3. Antianthrax serum was of benefit in one case. It was used in only two of our cases, being discontinued in one after rather severe reaction.

4. Guinea-pigs died within thirty-six hours after inoculation.

ANTHRAX AT CAMP DODGE, IOWA

REPORT OF THREE CASES, WITH BACTERIOLOGIC AND BLOOD STUDIES [*]

CARL G. DENNETT, M.D. (Saco, Maine)
First Lieutenant, M. C., U. S. Army
CAMP DODGE, DES MOINES, IOWA

The literature of anthrax reveals surprisingly meager attention paid to blood culture and cell count studies in this infection. The results of such studies in the cases here recorded may therefore prove of interest. The three soldiers of this camp affected with anthrax were admitted to the base hospital between Sept. 6 and Sept. 19, 1918. Of these, one died and two recovered. Two days previous to the earlier date a soldier had died immediately on entering the receiving ward, in whom the necropsy showed extensive intestinal anthrax.

REPORT OF CASES

Case 1.—Private A. C., white, aged 30, admitted, Sept. 12, 1918, had entered the service one week before. Before entering the service, he had been a car repairer. September 6, he noticed a pimple on the left cheek which was slightly painful. Three days later the pain was considerable and the lesion was discharging bloody serum. A few days before the appearance of the furuncle he had used a new shaving brush. Examination revealed a rather superficial induration the size of a dollar situated on the left cheek, 5 cm. from the angle of the mouth, with a dark red central eschar the size of a finger tip, discharging a serosanguineous fluid. The glands of the neck were not enlarged. The temperature was 98, the pulse 78, and respiration 22. Two cm. of 5 per cent. phenol solution were injected around the areola and 50 c.c. of pneumococcus serum (Rockefeller) given intravenously. Forty-eight c.c. of the serum were similarly given on the following day. This serum was administered in this and the other two cases by the attending ward surgeons because it was the only horse serum available, antianthrax serum not being immediately obtainable. Two days later the swelling began to subside and at the end of two weeks had disappeared. A mild conjunctival and nasal catarrh appeared eight days after the administration of the serum, which lasted a few days, followed by a general anaphylactic urticaria which persisted for a week. The temperature never rose above 99.6. Smears and cultures from the lesion were positive on the first two days and negative on the five succeeding examinations (Table 3). Daily blood counts revealed no leukocytosis (Table 1). The anthrax bacillus was demonstrated in culture of the shaving brush bristles, but this is not of value, as the patient had used the brush after the development of the lesion. Daily blood cultures were negative (Table 1).

Case 2.—Private P. B., white, aged 21, admitted, Sept. 11, 1918, had been a farmer before entering the service, but had not handled animals with discharging sores. He had used his present shaving brush two months. September 8, he experienced frontal headache and on the following day noticed a pimple on the left side of the neck about midway between the angle of the jaw and the chin. The swelling about the lesion began to increase at once, and there was pain which radiated down the left side of the chest and was aggravated by coughing. On admission the patient stated that he had vomited earlier in the day, and complained of severe headache and left pectoral pain aggravated by coughing and on deep breathing. The temperature was 101, the pulse 112, and respiration 26. On the left side of the neck immediately below the middle of the border of the inferior maxilla was an indurated area about the size of a quarter in the center of which an eschar with irregular edges and about the size of a dime was seen. Several vesicles surrounded the eschar and a serosanguineous fluid exuded from under it. An inflammatory and edematous areola surrounded the lesion and extended to the zygoma above and the clavicle below. This spread within a few hours to the hairline above and the level of the nipple below. There was also some extension to the right side of the neck. Except for a few moist râles over the left base, the lungs were negative. A smear from the discharge on admission showed the presence of the anthrax bacillus, and a pure growth was obtained on culture (Table 3). Three hours after admission, serum treatment was begun. Pneumococcus serum was given as follows:

September 11: 2:30 p. m., 20 c.c. subcutaneously in the pectoral region; 7 p. m., 30 c.c. subcutaneously in the pectoral region.

September 12: 11:30 a. m., 50 c.c. subcutaneously in the gluteal region; 6:30 p. m., 50 c.c. subcutaneously in the gluteal region.

September 13: 10:30 a. m., 85 c.c. intravenously.

On the evening of September 11, 0.5 c.c. of a 5 per cent. phenol solution was injected around the margin of the indurated area. The edema and inflammation began to subside, September 12, and had disappeared on the 14th. A few days later the induration and discharge were also gone, leaving a dry, black eschar, which had entirely healed, September 26. Slight cervical glandular swelling persisted until the patient's discharge, October 6. Blood cultures were positive for *B. anthracis*, September 11, 12 and 13, and negative thereafter. This, together with the daily white cell count, is shown in Table 1.

Case 3.—Recruit G. N., white, aged 29, admitted, Sept. 19, 1918, had entered the service two weeks before. He had been a farmer. Some of the cattle he had handled had had "pinkeye," but were not otherwise affected. September 16, while on the drill field, he noticed a papule on the right side of the neck near the angle of the jaw. On the following day he pricked the pimple, drawing blood and pus. On the next day he cut the sore while shaving with a razor which he had purchased at the regimental exchange ten days before. Soon after this the tissues around the lesion began to swell. On admission the patient complained of headache, and alternating hot and cold sensations. The temperature was 98, the pulse 78, and respiration 20. An indurated, slightly inflamed area about 7 cm. in diameter, with a central ulceration containing seropurulent fluid and covered with dried coagulum, was situated at the angle of the lower jaw on the right side. The cervical glands were enlarged. Moist râles were heard at both pulmonary apexes, and there was slight tenderness in the lower abdomen. A smear and culture made from the lesion on admission showed the presence of the anthrax bacillus. Four hours after admission the administration of serum was begun and given as follows:

---

[*] From the Laboratory of the Base Hospital.

September 19: 3 p. m., 50 c.c. of pneumococcus serum intravenously.

September 20: 9 a. m., 50 c.c. of pneumococcus serum intravenously; 10 p. m., 75 c.c. of pneumococcus serum intravenously.

September 21: 3 p. m., 35 c.c. of antianthrax serum intravenously.

September 19, at 5 p. m., 1 c.c. of 5 per cent. phenol solution was injected around the margin of the indurated area. September 21, the swelling extended to just above the root of the neck and about 2 inches to the left of the midline, causing some degree of dyspnea. The pulse was of poor quality. There was considerable epistaxis. The patient was restless throughout the following night. September 22, the epistaxis was repeated, and there was nausea, vomiting and abdominal pain. The pulse, however, was improved. The lungs were negative. The induration was somewhat smaller and the patient seemed on the whole better. Cultures were made that day of the vomitus and feces for the anthrax bacillus, the former proving negative and the latter positive. Bismuth subnitrate was given to control the vomiting. On the night of September 22, the patient was worse and was stimulated with strychnin and digitalis. He became extremely restless and somewhat delirious, and died at 6 a. m. Necropsy revealed involvement of Peyer's patches and the solitary nodules and considerable peritoneal exudate (about 1,500 c.c.). *B. anthracis* was recovered from the peritoneal exudate and obtained in pure culture from the heart's blood. The results of the blood studies in this case are given in Table 1.

TABLE 1.—BLOOD STUDIES

Date	White Blood Cells	Neutrophils	Small Lymphocytes	Large Lymphocytes	Basophils	Eosinophils	Blood Culture
Case 1:

9/21/18	12,400	87	11	2	..	..	Positive
9/22/18 Died.	16,000	84	16	..	..	..	Positive

Table 1 gives the results of the blood cultures, white blood count and differential cell count in all three cases. These were made daily until death in Case 3 and to recovery in Case 1 (except the third day). In Case 2, differential cell counts were made every day to recovery except on the first and fifth days of the disease, and blood cultures were taken daily to recovery except on the fifth day of the disease.

In making the blood cultures, about 12 c.c. of blood were placed in 150 c.c. of 0.5 per cent. glucose bouillon and incubated at 37.5 C. for twenty-four hours. A human blood agar plate and a tube containing 10 c.c. of 0.5 per cent. glucose bouillon were then inoculated from this culture and incubated at 37.5 C. In Case 3, these were positive at the end of twenty-four hours. In Case 2 the blood culture taken on the first day was negative at the end of the twenty-four hours' incubation, but positive after forty-eight hours. On the two subsequent days the blood cultures in this case were positive after twenty-four hours' incubation. In Case 1 no growth could be obtained from the blood culture at any time.

A study of Table 1 emphasizes the following interesting points:

1. The leukocytosis runs concurrently with the blood culture findings. Thus, Case 1, with blood cultures negative throughout the course of the disease, shows no leukocytosis at any time. Case 2 shows an increased white cell count on the first three days when the blood cultures were positive, falling to, and remaining at, normal as the blood cultures remained negative. In Case 3 a persistently positive blood culture runs parallel with a constantly rising leukocytosis, which is highest just before death.

2. The eosinophil count is in inverse proportion to the severity of the infection. Thus, in Case 1, the mildest, the average daily eosinophil count for the thirteen days is 8.5. In Case 2 the average for the first three days, which represent the more active stage of the disease, is 1; the average for the subsequent eleven days, representing the declining stage, is 4. In Case 3, with a high grade infection throughout, the average eosinophil count is 1. This is shown more graphically in Table 2, in which the daily average for the three cases is computed from the figures in Table 1.

TABLE 2.—AVERAGE DAILY COUNT

	White Blood Cells	Neutrophils	Eosinophils
Case 3	11,650	82	1
Case 2:			
During first three days	11,600	79	2
During subsequent days	7,900	72	4
Case 1	7,300	70	8.5

Case 1 was examined for intestinal parasites as a possible cause for the eosinophilia and found negative.

It may be of interest to note that the leukocytosis bears a direct relation to the clinical course. Thus, in Case 1 the cell count was always normal. In Case 2 the count becomes normal as the fever falls and the swelling subsides, while in Case 3 the leukocytosis persists throughout, being highest on the day preceding death. At no time was phagocytosis observed.

Table 3 gives the result of the smears and cultures taken from the lesions. *B. anthracis* was obtained in pure culture on the first day in all three cases. After the first day, Case 1 also showed short chain nonhemolytic streptococci and staphylococci; Case 2 showed pneumococci, and Case 3 *Micrococcus catarrhalis* and staphylococci. The smears from the lesion showed gram-positive bacilli with square ends about 6 by 1.5 microns, occurring in pairs. The smears from the cultures showed nonmotile bacilli which were gram-positive, some having rounded ends and others square, containing spores in the center and occurring in long chains. The cultures were made on human blood agar plates, and under low power the colonies appeared as dense, irregularly rounded masses from which spread parallel, wavy strands, which under high power were seen to consist of chains of bacilli, each bacillus containing an oval, glistening body in the center.

Culture of the urine was negative in all three cases. The feces were negative in Cases 1 and 2 and positive on the day preceding death in Case 3.

Cultures were made of the bristles of the shaving brushes used by all three patients, and only that of Case 1 was found positive. This, however, as stated before, was of little significance, as the brush had been used after the appearance of the lesion.

ANIMAL INOCULATION

An emulsion made from the growth obtained by blood culture in Case 2 was injected into a guinea-pig. The animal died in thirty-two hours, and *B. anthracis* was obtained in pure culture from the heart's blood and spleen, and also recovered from the peritoneal exudate. Cultures were also made from the lesion in each case and injected into guinea-pigs. The animal in Case 1 died in thirty-two hours, in Case 2 in twenty hours, and in Case 3, forty-six hours. In each animal, pure growth of *B. anthracis* was obtained from the heart's blood and spleen and, in combination with various pyogenic organisms, from the peritoneal exudate.

TABLE 3.—SMEARS AND CULTURES FROM LESIONS

Date	Smear	Culture
Case 1:		
9/10/18	B. anthracis	B. anthracis in pure culture
9/13/18	B. anthracis; nonhemolytic streptococci	B. anthracis; nonhemolytic short chain streptococci
9/14/18	Nonhemolytic short chain streptococci and staphylococci	Nonhemolytic short chain streptococci and staphylococci
9/14/18	Nonhemolytic short chain streptococci and staphylococci	Nonhemolytic short chain streptococci and staphylococci
9/16/18	Nonhemolytic short chain streptococci and staphylococci	Nonhemolytic short chain streptococci and staphylococci
9/21/18	Nonhemolytic short chain streptococci and staphylococci	Nonhemolytic short chain streptococci and staphylococci
9/22/18	Nonhemolytic short chain streptococci and staphylococci	Nonhemolytic short chain streptococci and staphylococci
Case 2:		
9/11/18	B. anthracis	B. anthracis
9/12/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/12/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/13/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/14/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/16/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/18/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/21/18	B. anthracis; pneumococci	B. anthracis; pneumococci
9/22/18	B. anthracis; pneumococci	B. anthracis; pneumococci
Case 3:		
9/19/18	B. anthracis	B. anthracis
9/20/18	B. anthracis, Micrococcus catarrhalis and staphylococci	B. anthracis, Micrococcus catarrhalis and staphylococci
9/21/18	B. anthracis, Micrococcus catarrhalis and staphylococci	B. anthracis, Micrococcus catarrhalis and staphylococci
9/22/18	B. anthracis, Micrococcus catarrhalis and staphylococci	B. anthracis, Micrococcus catarrhalis and staphylococci

In view of the distinctive appearance of the anthrax colonies, which makes them easily obtainable in pure culture, and of the high susceptibility of the guinea-pig, toward this organism, which can be recovered from the guinea-pig in pure culture, the confirmation of the diagnosis of anthrax should be easy. Ludy and Rice[1] report a case of anthrax in which they experienced great difficulty in confirming the diagnosis by animal inoculation.

It will be observed that in our three cases, anthracemia was demonstrated in two. Graham and Detweiler[2] report the recovery of a patient in whose blood they found the anthrax bacillus. The rarity in literature of demonstrated anthracemia may be due to a lack of bacteriologic investigation.

HEMOLYTIC STREPTOCOCCI

A SEROLOGIC STUDY OF STRAINS ISOLATED DURING A RECENT EPIDEMIC AT CAMP WADSWORTH, S. C.: PRELIMINARY REPORT

CLAUDE D. HAMILTON, M.D. (Canton, Ohio)
Captain, M. C., U. S. Army

AND

LEON C. HAVENS, M.D. (Cambridge, Mass.)
First Lieutenant, M. C., U. S. Army

CAMP WADSWORTH, SPARTANBURG, S. C.

The experiments embodied in this report deal with cultural and serologic studies of hemolytic streptococci isolated in the recent epidemic of respiratory diseases at Camp Wadsworth, S. C. These cultures were obtained from (1) healthy carriers, (2) patients with acute bronchitis and (3) patients with bronchopneumonia, both from the sputum during the course of the disease and from the lungs and heart's blood at necropsy.

A study of the healthy carriers of hemolytic streptococci has been interesting. From June, 1918, to Oct. 1, 1918, when the number of cases of respiratory infections reached epidemic proportions, 21,000 throat cultures were taken from the various units in camp. Chart 1 shows the percentage of healthy carriers found. It will be seen that the curve shows a rather steady rise till the latter part of September, when it rose above 20 to 25 per cent., following which the number of cases of respiratory diseases assumed epidemic proportions. Following this outbreak the number of carriers suddenly dropped to the level obtaining during the summer months.

The hemolytic streptococci are known to be secondary invaders of no mean importance in measles[1] and other acute infections, and it would seem from a study of the recent epidemic of influenza that its importance in causing pneumonia is not to be disregarded.

Previous studies of hemolytic streptococci have resulted in a rather chaotic condition of our knowledge of the different strains of this organism. Park and Williams[2] have classified the hemolytic streptococci in different groups according to their sugar reactions.

It will be shown later in this report that the cultural characteristics have but little bearing on their serologic grouping.

Kinsella and Swift,[3] from a study of a limited number of strains, came to the conclusion that, so far as complement fixation was concerned, all strains were identical.

The purpose of the present study is to show that the hemolytic streptococci can be grouped, according to their agglutination reactions, into certain more or less definite types, and that furthermore, a protective serum for each group is possible of production.

Heretofore little attention has been paid to the different types of streptococci in the production of antistreptococcic serum. It has been the custom to use as many strains of streptococci as possible, with the production of a polyvalent serum. This serum, however, has not been potent, since it has not coincided with the strains causing the infection.

In this study the cultural and serologic characteristics of 110 cultures of hemolytic streptococci from different sources have been studied. The sources from which these strains have been obtained are shown in Table 1. In addition thirty-six cultures from new arrivals in camp were studied to ascertain whether we were dealing with only a limited number of strains in our study; as will be shown later, these strains corresponded both culturally and serologically with those isolated from camp inhabitants.

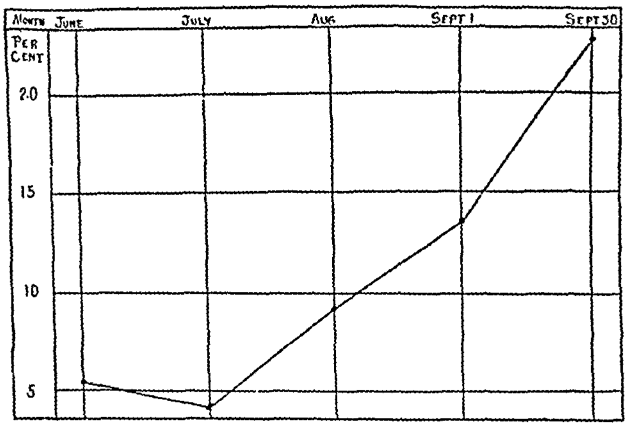

Chart 1.—Percentage of healthy carriers of hemolytic streptococci, Camp Wadsworth, S. C., from June to September, 1918.

TABLE 1.—SOURCES OF STRAINS

	Number Examined	Number Strains Isolated
Healthy carriers	4,143	48
Acute bronchitis	3,817	33
Bronchopneumonia (sputum)	113	11
Bronchopneumonia (necropsies)	45	18
Total		110

CULTURAL CHARACTERISTICS

Many of the strains differ in the appearance of the colonies on blood agar. The size of the colonies and the degree of hemolysis varies with different strains. All strains grow poorly in plain broth, but grow fairly well in glucose broth to which 10 per cent. blood has been added. The character of the growth is usually a uniform clouding with a slight tendency in some strains to flocculate and sediment.

The sugar reactions are indicated in Table 2. It will be seen that the majority of the strains are identical as far as their ability to split sugars is concerned.

TABLE 2.—SUGAR REACTIONS OF HEMOLYTIC STREPTOCOCCI

	Lactose		Mannite		Salicin		Inulin		Total
	+	—	+	—	+	—	+	—	
No. of strains	110	0	0	110	84	26	0	110	110

SEROLOGIC EXPERIMENTS

While the grouping of these strains of hemolytic streptococci by means of their agglutination reactions is not yet complete, the indications are that there are at least four groups that are fairly distinct. Chart 2 shows graphically the relation between the different groups. It will be seen that 48 per cent. of these 110 strains are agglutinated in high dilution (1:5,000) by the serum used, and that there are three other groups, depending on their degree of agglutinability with this serum.

It has been found fairly easy to produce in rabbits a high titer serum. Live avirulent cultures were used for immunization. Nine intravenous injections were found to be sufficient to produce an immune serum which agglutinated homologous strains in dilutions of 1:10,000.

Glucose broth with 1 per cent. blood was used for growing the cultures for agglutination tests. In this medium an abundant growth is obtained in from sixteen to twenty-four hours. Very few of the cultures failed to grow with a uniform turbidity suitable for agglutination purposes.

BACTERICIDAL TESTS

Having found that this serum was high in agglutinins, it was interesting to determine its bactericidal properties. It was found that the bacteriolysins were specific for each group in the same way as the agglutinins are specific. Strains that were identical by agglutination tests were killed, while the immune serum failed to have bactericidal properties outside of its own group. Table 3 gives the results of bactericidal tests. In all of the experiments, 0.5 c.c. of a 1:10 dilution of immune serum and 0.5 c.c. of a 1:10 dilution of fresh guinea-pig complement were mixed with 0.5 c.c. of a twelve hour blood glucose broth culture of the streptococcus strain. Control tubes contained 0.5 c.c. culture, 0.5 c.c. complement and 0.5 c.c. salt solution. The tubes were then incubated four hours. A loopful from each tube was then plated and the number of colonies counted after twenty-four hours' incubation.

TABLE 3.—BACTERICIDAL EXPERIMENTS

No. of Culture	No. of Colonies: Serum plus Complement	No. of Colonies: Salt Solution plus Complement	Agglutination
159	0	800	1:5,000
161	0	200	1:5,000
170	0	200	1:5,000
164	0	200	1:5,000
163	0	600	1:5,000
169	50	1,000	1:5,000
186	10	200	1:5,000
172	100	2,000	1:5,000
168	24	28	1:40
187	500	500	1:20
184	500	500	1:60
188	200	200	1:20
181	200	200	1:40
178	200	100	1:20

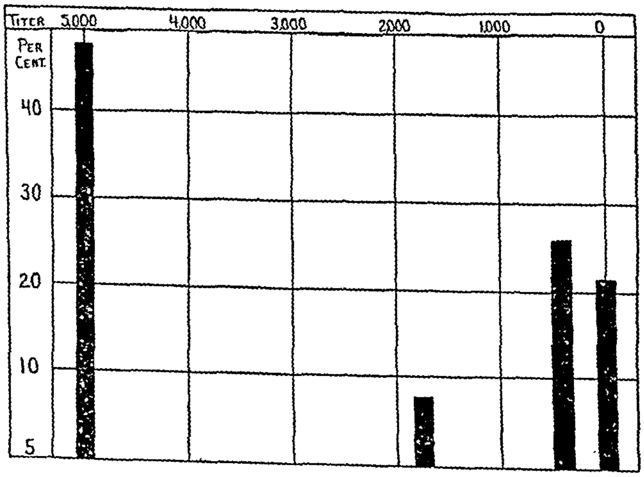

Chart 2.—Agglutination of hemolytic streptococci—110 strains.

These experiments show that the serum is potent only for the homologous strains, and has no more effect than normal serum against strains of other groups.

PROTECTION EXPERIMENTS

The foregoing experiments give evidence of the immune properties of the serum in vitro. The question next arose as to whether the serum was of value in protecting animals against infection with hemolytic streptococci. Mice were used in these experiments. Strains 159, 192 and 197, which had been found to fall within the group which was agglutinated in high dilution, were used. These strains were passed through mice until their virulence was such that 0.5 c.c. of a four hour blood broth culture killed within twenty-four hours. The protocols give the results of these protective experiments. It is necessary to use a sufficient amount of serum to neutralize the bacteria, which may account for its failure to protect Mice 2 and 4. Furthermore, Culture 159 was a highly virulent strain; 0.1 c.c. of a four hour blood glucose broth culture often killed a mouse in twelve hours.

PROTOCOLS

Mouse 1.—Control. At 2 p. m., 0.25 c.c. of a four hour blood glucose broth culture of Strain 159. Inactive and sick at 6 p. m. Died during the night in less than eighteen hours.

Mouse 2.—At 2 p. m., 0.25 c.c. of a four hour blood glucose broth culture of Strain 159 and 0.25 c.c. serum. Normal at 8 p. m. Dead at 8 a. m.

Mouse 3.—Control. At 8 a. m., 0.1 c.c. of a six hour blood glucose broth culture of Strain 159. Sick at 12 m. Dead at 9 p. m.

Mouse 4.—At 8 a. m., 0.1 c.c. of a six hour blood glucose broth culture of Strain 159 and 0.5 c.c. serum. Normal at 4 p. m. Dead in twenty-four hours.

Mouse 5.—Control. At 2 p. m., 0.5 c.c. of Culture 197. Dead in thirty-six hours. Peritoneal exudate showed many streptococci, very few leukocytes.

Mouse 6.—At 2 p. m., 0.5 c.c. of Culture 197 and 0.5 c.c. serum. Normal in thirty-six hours. Dead in seventy-two hours. Peritoneal exudate showed active phagocytosis of streptococci.

Mouse 7.—At 2 p. m., 1.0 c.c. serum. At 3 p. m., 0.5 c.c. Culture 197. Normal seventy-two hours later.

Mouse 8.—Control. At 9 p. m., 0.5 c.c. Culture 192. Dead fourteen hours later.

Mouse 9.—At 9 p. m., 0.5 c.c. Culture 192 and 0.5 c.c. serum. Normal seventy-two hours later.

Mouse 10.—Control. At 3 p. m., 0.5 c.c. Culture 197. Dead sixteen hours later.

Mouse 11.—At 3 p. m., 0.5 c.c. Culture 197 and 0.5 c.c. serum. Normal twenty-four hours later.

Mouse 12.—At 3 p. m., 1 c.c. serum. At 4 p. m., 0.5 c.c. Culture 197. Normal twenty-four hours later

From these experiments it seems that an antistreptococcic serum may be produced in rabbits quite easily. Furthermore, this serum is high in agglutinins, bacteriolysins and other protective properties, provided the serologic differences between strains is observed.

SUMMARY

1. Hemolytic streptococci can be grouped into a few rather definite types.

2. These groups are obtained by the serologic reactions of the different strains, since their cultural characteristics bear no relation to their immunologic grouping.

3. The serums of rabbits immunized with a strain of hemolytic streptococcus protect mice against infection with a homologous strain, but not against strains which are serologically different.

4. Certain "master strains" can be isolated by their serologic reactions, and it seems possible that these strains may be used in the production of a therapeutic serum for use in infection with hemolytic streptococci.

Clinical Notes, Suggestions, and New Instruments

SELECTIVE ELIMINATION OF HAY BACILLUS FROM CULTURES OF OBLIGATIVE ANAEROBES

Ivan C. Hall, M.S., Berkeley, Calif.
Associate Professor of Bacteriology, University of California Medical School

Repeated plating and streaking out on agar plates are universally acknowledged to be fairly reliable procedures for the isolation of aerobic bacteria irrespective of the possible concurrence of obligative anaerobes, for the latter, if present, are completely eliminated by the conditions of aerobic culture. But the same procedures applied under anaerobic conditions for the isolation of obligative anaerobes from cultures mixed with aerobes involve much uncertainty owing to the fact that many aerobes are also facultative anaerobes. It is therefore necessary to eliminate all aerobes from the culture before attempting the purification of obligative anaerobes by any method of surface colony isolation. It is an easy matter to eliminate nonsporulating contaminations by heating cultures containing sporulating anaerobes to a temperature sufficient to destroy vegetative forms alone; but selective heating is a total failure for the elimination of hay bacilli, since most of these organisms are less susceptible to heat than the spores of anaerobes. In view of the relative infrequency with which anaerobes are encountered naturally free from aerobes, and the possibility of aerobic contamination of pure cultures of anaerobes in the laboratory, the method of eliminating aerobic spores here described may be of interest.

The method consists in repeated transfer with incubation of cultures in glucose broth with 1:100,000 or less of gentian violet. The broth is contained in our constricted tube with marble seal;[1] this, while most convenient, is not considered indispensable in the method.

The tubes of dye medium are heated in a cup of boiling water for a few moments, to drive out dissolved oxygen, and are cooled just previous to inoculation. Growth of anaerobes is likely to be delayed and restricted in the presence of gentian violet as compared with nondye medium. Transfer should be made by loop or pipet, as soon as definite turbidity appears, to an aerobic agar slant, gentian violet glucose broth (boiled and cooled), and deep sterile brain (boiled and cooled). The first is a test for the presence of aerobes, the second provides for continuation of the process if so far unsuccessful, and the third secures a viable culture in the case of successful elimination of aerobic spores. Usually not more than three transfers in gentian violet glucose broth are necessary to eliminate hay bacilli from the culture. Confirmation of freedom from aerobic organisms should be made also in the case of the brain culture by attempted culture on an aerobic agar slant. Similar results may be secured with crystal violet.

Cultures so freed from aerobic forms may yet comprise two or more species of anaerobes so that purity of anaerobic cultures cannot be postulated, as is so often done, on failure to secure aerobic growth therefrom.

It may seem paradoxical that we should advocate the use of these dyes in this manner after having only recently shown the value of gentian violet in the elimination of spurious presumptive tests for B. coli in water[2] and milk[3] due to anaerobes. The procedure is based, however, on the fact that while most anaerobic spore-bearing bacilli are gram-positive and follow Churchman's[4] rule in being inhibited by

triamino-triphenyl-methane dyes, they are apparently considerably less susceptible to the action of such dyes than aerobic sporulating bacilli. The same reagent can therefore be made to operate in a different sense with respect to the selective cultivation of anaerobic bacilli, according to the concentration of the dye used.

The principle has been used many times with various mixtures of anaerobes and hay bacilli without, as yet, a single failure. Even *B. putrificus*, which of all anaerobic bacteria cultivated by us is slowest growing and most delicate, has been freed from accidental hay bacillus contamination in two transfers by this method.

Our recent work with gentian violet and crystal violet has been done with a stock of Grübler's dyes secured before 1914. I hope that whatever is significant in this work can soon be repeated and corroborated by means of American made dyes so that when prewar stocks are exhausted there will be no temptation to renew our patronage of German dyestuffs.

A NEW METHOD FOR FIXATION OF PARAFFIN SECTIONS

James Hebert Mitchell, M.D., Chicago

A new method for the fixation of paraffin sections to slides, doing away with the troublesome albumin fixative, has been devised by Land[1] which depends on the well known principle that most colloidal substances when treated with a solution of a salt of chromium, exposed to light and dried, become insoluble in water. In his paper Land described his technic as follows:

> A 1 per cent. solution of acacia that has been made slightly yellow by the addition of a few drops of 0.2 per cent. potassium bichromate is allowed to flow over a thoroughly clean slide. The paraffin ribbon is then placed on this slide and exposed to light until dry.

In working with this method I found that the paraffin sections were invariably fixed to the slide after a few hours' exposure to light. The fixative used in this manner, however, had the disadvantage of taking up too much stain, particularly with polychrome methylene blue, which is used frequently in dermatologic work. Later I adopted the practice of moistening a cotton swab with the acacia and bichromate solutions, pressing out as much of the solution as possible from the swab, and then rubbing it very lightly over the slide so that the mixture dried immediately and could scarcely be detected with the eye.

I have found that through this use of a mere trace of the fixative, the sections adhere equally well as when the slides are flooded; moreover, there is no taking up of stain by the fixative.

25 East Washington Street.

A Unique Eye Case.—This case, though suggesting that foreign bodies may be a cause of dacryocystitis, is of interest chiefly because of its rarity. The patient complained of soreness and irritation in his right eye awakening him early in the morning. His wife clipped off what she assumed to be an inverted eyelash, scratching the eyeball. As he was not relieved he came to the dispensary on the way to his office. Several medical officers who examined him observed hyperemia of the ocular conjunctiva limited to the sector near the inner canthus, but did not discover the cause. The patient received an eye wash and was instructed to return if the symptoms did *not subside*. Several hours later when he came back, a black speck was discovered in the orifice of the inferior canaliculus, which when magnified by a lens, appeared to be the stump of a misplaced or displaced eyelash. With the aid of the magnifying glass it was grasped with forceps and drawn out of the canaliculus without any resistance. It was a fragment of an eyelash, three-eighths inch long. Relief was immediate.—G. W. Haigh, M.D., Lieutenant, M. C., U. S. N. R. F., Navy Yard, Boston.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

DIGITAN.—First introduced as digipuratum.—A digitalis preparation said to contain digitoxin and digitalin in the form of tannates. It is standardized biologically by the method of Gottlieb. It is claimed that in digitan 85 per cent. of the inactive substances found in the ordinary extract have been removed and that it is free from digitoxin.

Actions and Uses.—The same as those of digitalis.

Dosage.—The same as that of digitalis.

Manufactured by Merck & Co., New York, under U. S. patent No. *943,578* (Dec. 14, 1909; expires 1926) by license of the U. S. Federal Trade Commission.

Digitan Tablets, 1½ grains.—Each tablet contains digitan 0.1 Gm. (1½ grains).

Digitan is obtained by removing objectionable constituents from an alcoholic extract of digitalis, neutralized with alkaline hydroxides, by the addition of ether, petroleum benzene, or other suitable precipitant, and reducing the purified liquid to a powder, by evaporating with milk-sugar.

Digitan is a greenish-yellow, odorless powder of bitter taste. The active constituents of digitan are insoluble in cold water and diluted acids, but are easily soluble in weak alkalis.

Digitan responds to the following identity test: If 0.1 Gm. digitan is underlaid with about 3 Cc. of glacial acetic acid which contains 1 per cent. of a 5 per cent. solution of ferric sulphate, there appears a red band (presence of digitalin) and above this another, at first bright green, later changing to dark green and finally blue (presence of digitoxin). To determine the digitoxin content, 10 Gm. of digitan are dissolved with moderate heat in 50 Cc. of water; 5 Cc. or 10 per cent. ammonia water are added and the liquid is then extracted with chloroform. The chloroformic extractions are filtered into a tared vessel and the chloroform removed by distillation. The residue is dissolved in 3 Gm. of chloroform and mixed with 7 Gm. of ether and 50 Gm. of petroleum ether. The separated flakes are collected on a small filter. Then the residue on the filter is dissolved in absolute alcohol, allowing the solution to run into the tared distilling vessel. The alcohol is then distilled off and the residue dried to constant weight. The digitoxin thus found should not amount to more than 0.04 Gm. The physiologic activity is determined by the method of Gottlieb: 1 Gm. of digitan is treated with 19 Cc. of hot water and 1 Cc. of a 2 per cent. solution of sodium bicarbonate. If now 0.15 Cc., 0.2 Cc., and 0.25 Cc., respectively, of this solution is injected into the femoral lymphatics of freshly caught land frogs (*Rana temporaria*), weighing 30 Gm. each, the exposed heart of the animals should permanently be brought to a stop in the majority of instances (say in five out of six experiments) within half an hour after the administration of a 0.2 Cc. dose. If 0.2 Cc. of the 5 per cent solution (containing 0.01 Gm. of digitan) is sufficient to stop the [illegible] within half an hour, then 1 Gm. of digitan will contain 100 units; should 0.25 Cc. of the 5 per cent. solution be necessary, the number of units of digitan it contains would be 80; if 0.25 Cc. should not yet prove sufficient, the preparation would be too weak to be effective; and should the systole be arrested after a dose of 0.15 Cc. within half an hour after injection, the preparation would be too strong. The total physiologic activity having been determined, the relative amount that is due to digitoxin can be determined by using the digitoxin separated in the foregoing quantitative determination and by the difference between this amount and the total physiologic activity the amount due to the digitalin alone can be estimated.

NEOARSPHENAMINE (See New and Nonofficial Remedies, 1918, p. 47).

Neoarsenobenzol (Dermatological Research Laboratories).—A brand of neoarsphenamine.

Manufactured by the Dermatological Research Laboratories, Philadelphia Polyclinic, Philadelphia, Pa., under U. S. patent reissue No. 13,848 (Dec. 15, *1914*; expires 1931) by license of the U. S. Federal Trade Commission.

Neoarsenobenzol (Dermatological Research Laboratories) 0.1 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.1 Gm.

Neoarsenobenzol (Dermatological Research Laboratories) 0.3 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.3 Gm.

Neoarsenobenzol (Dermatological Research Laboratories) 0.45 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.45 Gm.

Neoarsenobenzol (Dermatological Research Laboratories) 0.6 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.6 Gm.

Neoarsenobenzol (Dermatological Research Laboratories) 0.75 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.75 Gm.

Neoarsenobenzol (Dermatological Research Laboratories) 0.9 Gm. Ampules.—Each hermetically sealed ampule contains neoarsenobenzol (Dermatological Research Laboratories) 0.9 Gm.

THE SUPPLY OF PRACTICAL NURSES

What's the matter with the trained nurse? A wave of harsh and resentful criticism of the professional nurse seems to be sweeping over the country. In spite of a recognition of her splendid achievement in remaking hospital nursing, and of setting up high standards for private nursing; in spite of her magnificent and sacrificial service in the great war, she is not now viewed by large numbers of physicians and laymen as a ministering angel of mercy or as an unmixed blessing. And when rebuked for these harsh expressions of disapproval, her unfeeling critics forcefully reply: "She is getting just what she deserves." What does it mean?

Is it because through high standards of admission to her schools, and long years of training before she is graduated, she has chosen to make herself one of a small body of the elect, a superior being? Is it because with the high cost of living and the scarcity of these chosen few she has, labor-union-like, demanded higher pay which only the well-to-do can give? Is it because in the home she is autocratic and unwilling to serve except in accordance with rules that she herself lays down, often demanding that service be rendered her and causing discord in the household management at a time of crisis? Is it because in many hospitals she has gradually acquired more influence and power until through her officials she speaks with authority even to the management, and dictatorially demands that before the interests of the medical staff are considered—sometimes even before the interests of the patients—there must be considered those of the nurses? Perhaps there is a little truth in each one of these reasons. Perhaps in this resentful criticism, narrow as it may be, the nurses are reaping what they have sown.

The war and the epidemic of influenza, with the consequent scarcity of nurses, have acutely drawn attention to the trained nurse and to the fact that she does not supply the suitable agent for ministering to the large body of the ill. The very poor may get free nursing in the hospitals or, if lucky, at their homes through charity; the rich can and will pay whatever may be demanded; but the large mass of people of moderate means, too self-respecting to accept charity, not able to pay the high price of the expert nurse, must be deprived of her services or secure them at what to these people is often a ruinous sacrifice. More than this: a nurse of the highly trained type is not necessary or even desirable in the vast majority of cases of illness.

What are the requirements of a capable, skilled nurse, a physician's assistant? First a right personality; without this she is hopeless. Then intelligence, by which we mean a readiness of comprehension and understanding. Further, she should be of fair education, able to make herself understood, to write, to read, to reason. Lastly, she should have had training of sufficient length, probably one year, in a good hospital. This training should teach her the proper bed care of the ill, the preparation of food, the management of the patient—not his illness—and the methods of administering drugs and other remedial agents. She should learn enough of anatomy so that she will not, with her hypodermic syringe, enter the brachial artery; she should know enough of symptomatology to sense the possible significance of blood in the stool or of abdominal pain in typhoid; she should know enough pathology so that she will not wilfully violate the physician's orders against massaging a thrombosed femoral vein; she should have enough theoretical and practical training in bacteriology so that aseptic methods are to her, through her grasp of the reasons underlying them, methods to be scrupulously followed.

It goes without saying that other things—personality, native intelligence, etc.—being equal, the college or high school graduate will grasp these facts more readily and will, to this extent, be the more competent nurse. But such superknowledge is not necessary. For 90 per cent. of cases of illness, a skilled nurse with the characteristics just enumerated and with one year's training will answer fully as well and will fit into the average household better. She will be a true physician's assistant and will be a household helper not too proud to assist in the kitchen or even to help care for the baby. If this is true, why should not this capable woman of ordinary but sufficient ability and training be allowed to practice her profession licensed by the state and earning an honorable livelihood?

There is a place for the highly trained nurse, the registered nurse of today. From their ranks will come the superintendents of the training schools of various grades, the head nurses in our hospitals, the nurses in our operating rooms, nurses for cases of special severity or complication, and the teachers of nurses. Let the training schools preserve their high ideals, though there may be question as to the necessity or wisdom of requiring even a high school degree for admission or a three years' course of training except in special cases or for postgraduate work. For her own good let the nurse be a little less autocratic, a little less dictatorial, a little more human. *Non ministrari sed ministrare* is as good a motto for a training school as for a woman's college. The trained nurse from having been a luxury has become a public necessity, like the telephone and railroad. Should not methods less like those of selfish private ownership give way to those wherein service to the sick public is the paramount aim?

MEDICINE IN THE NEW WORLD OF PEACE

We have frequently emphasized the fact that medicine and those who practice it can never be the same after the war as before. We fully recognize that we are in the presence of a great social upheaval whose effect throughout the world will probably surpass even that momentous event known as the French Revolution. We can see only dimly whither we are tending, but it is at least evident that civilization is moving rapidly, whether down a steep place into the sea or, as some believe, up into the heights of the Promised Land. In this movement the medical profession is to a degree caught in the sweep of forces beyond its control, but it is also to a large extent potent and responsible for the part it shall play in the new era dawning on us. Many individual physicians have been more or less completely, if temporarily, uprooted by mobilization for war, and the whole medical profession, like many other professions, has been jostled out of its stability and routine. It is a time to many for strenuous readjustment; it is also an unequaled opportunity for surveying the future of medicine and formulating plans for a rational development. One thing is certain: that no limited considerations of self interest are going to satisfy either the bulk of medical practitioners or the public they serve. The practice of medicine will more than ever be regarded not merely as a means of earning a livelihood but as an essential service to mankind.

It would not be desirable to consider here all the possibilities of change, even could we envisage these possibilities. But there is at least one aspect of medicine that the future is very certain to bring still more into the foreground: This is the side of medicine that is concerned with the prevention of disease, the preservation of the public health. Like many truths that have become wearisome through reiteration, the doctrine that from the standpoint of the community the prevention of disease is more important than its cure has come to sound dully on our ears. It has been said so often that many of us feel that we have done something about it. And yet every student of public health knows that hardly a beginning has been made in the application of our existing knowledge to the solution of public health problems. Available information is not utilized; suitable procedures are not carried out at all or are carried out wastefully and inefficiently; the opinion of the amateur or of the facile newspaper hygienist has as much weight with the public as the opinion of the expert.

These are all familiar conditions, but the medical profession has thus far failed to consider the situation seriously enough. The creation and proper maintenance of a national department of health would undoubtedly help toward the more general recognition of the importance of preventive medicine, but at best this would be only a preliminary. The real reform must be based on the training of a sufficiently large number of men in the principles of public health so that a body of educated, expert opinion in the medical profession will appreciate what can be done and what ought to be done, and will stand solidly back of attempts to introduce public health measures and to strengthen public health organization. Thus far, as everybody knows, little has been done to expand the work in preventive medicine in many of our leading medical schools to a degree at all commensurate with its importance in the future of American medicine.

The situation is simply this: Civilized peoples are spending vast sums in the work of palliating and remedying the results of disease, and relatively little in preventing disease. Reconstruction of ravaged territory is sometimes necessary; but a world with eyes fixed on a peace congress does not need to be told that our main concern is to choke off the agencies of devastation before they become operative. The responsibility of laying much more stress than heretofore on the prevention of disease rests primarily on the medical profession. There are at least two ways in which the conspicuousness into which the war has thrown this side of medicine can be immediately utilized in furthering the interests of public health: One is the support of public health authorities by individual physicians. The other is the frank, efficient and immediate recognition of the importance of preventive medicine in the curriculums of our medical schools.

THE METABOLISM OF NONSPECIFIC INFLAMMATORY PROCESSES

The entrance of various micro-organisms into the body, particularly when their invasion is localized in such ways as to give rise to septic inflammations, is attended by well recognized, pronounced reactions. These are varied and may include fever, loss of weight and leukocytosis, along with marked disturbances in nitrogenous metabolism. Ordinarily it is assumed that this untoward response is due to the toxins or other ill defined and undefined products of the invading bacteria—a specific reaction. Thus in such types of septic inflammation as septicemia, peritonitis and pneumonia there is in addition to more familiar clinical manifestations a definite rise in the nonprotein and urea nitrogen of the blood.[1] Some cases show a great rise above normal (more than 100 mg. of nonprotein nitrogen per hundred c.c. of blood), without evidence of kidney lesions sufficiently severe to indicate retention of metabolites as the cause of the high figures cited.

Whipple[2] and his associates of the Hooper Foundation for Medical Research at the University of California have submitted evidence to show that suppurative processes or acute inflammation due to a chemical irritant can bring about the same changes as those represented by the inflammatory reaction caused by some specific bacterial agent, *when the latter is* limited to the initial location. Evidently nonspecific intoxication must account for the sterile reactions produced. Whipple has accordingly formulated the hypothesis that the injury done by means of a sterile abscess may be made up mainly of two factors: (1) a local injury of tissue by the chemical irritant, and (2) general injury of body protein by means of toxic split products absorbed from the site of local injury. That is, the locally injured cell protoplasm undergoes prompt autolysis with escape of toxic protein cleavage products. Since septic inflammations show an almost identical acute reaction and injury of body protein, the deduction is obvious that "a great part, at least, of the reaction in septic inflammation is truly nonspecific and results from the primary injury of the host's protein and cell autolysis."

This view is by no means an orthodox one. It is in good part based on Whipple's finding that in the intoxication following intestinal obstruction there is a very marked increment in the nonprotein nitrogen of the blood. Whipple claims to have isolated a "toxic proteose," injection of which causes a profound disturbance of tissue equilibrium as indicated by the altered nitrogenous metabolism. With Van Slyke[3] he has observed that these changes are identical with those following the feeding of large amounts of protein. These facts, Whipple and Van Slyke remark, indicate that the proteose intoxication causes an abnormally rapid autodigestion of tissue proteins, but that the nitrogenous end-products are, in chief part at least, the same that result from normal catabolism of food proteins. There is no evidence, they add, that the autolytic products play any part in causing the intoxication. The possibility of such a part and a resultant vicious circle is not excluded, but from the available facts the autolysis appears more as a result than a cause of the intoxication. It seems possible, to Whipple and Van Slyke, that in disease or intoxication, tissue catabolism may be enormously accelerated and yet yield the end-products of normal protein breakdown.

We may agree that the interesting results following injection of a sterile substance represent a good example of accelerated protein catabolism and tissue autolysis caused by the action of a toxin, uncomplicated by the presence of parasites, by abnormally high temperature, or by any other apparent factors save the toxin itself. The analogy—to describe the facts in a purely objective way—between the manifestations of septic inflammations and nonbacterial reactions unquestionably emphasizes most prominently the nonspecific nature of the responses in many supposedly specific infections or processes. But we may be justified in hesitating to identify the materies morbi in all these cases with an ill defined proteose until the physiologic chemistry of this aspect of the subject is pursued somewhat farther.

CENTENARY OF THE AMERICAN JOURNAL OF SCIENCE

It would be unfortunate indeed if the distractions of the world war and the enormous demands made by it on the energies of men in medicine compelled them to overlook entirely what would have been, in peace times, a significant event. Last July the *American Journal of Science,* familiarly known for many years as *Silliman's Journal,* celebrated its centennial. This is the only scientific periodical in this country to maintain an uninterrupted existence since that early date, and this honor is shared with hardly more than half a dozen other independent scientific periodicals in the world at large. Similar publications of learned societies for the same period are also few in number. The history of the enterprise, together with reviews of the century's progress in the fundamental physical, chemical and biologic sciences, written by eminent men of science, has been published in an anniversary issue.[1]

Amid the wealth of contributions that a hundred years have afforded in the form of papers or reviews on almost every field of scientific endeavor, and even to some extent outside of this precise domain, we feel impelled to mention two items of singular interest to medical readers. One of these pertains to the description of chloroform by Samuel Guthrie of Sackett's Harbor, N. Y. In a letter published in *Silliman's Journal* in 1832,[2] he describes a "cheap and easy process" for preparing "*chloric ether*" (chloroform), having been impelled thereto by reading of its possible

medicinal powers in Silliman's "Elements of Chemistry." Silliman himself records in the same volume of his journal (p. 405) that he was in the habit of preparing "an alcoholic solution of this ether," diluting it with water to the proper degree, and then calling the attention of the medical students to its remarkably grateful properties as a cordial, suggesting at the same time the probability that it might prove a valuable medicine. Dr. Eli Ives, professor in the Medical Institution of Yale College in 1832, reported favorable effects of the administration of "chloric ether" both by mouth and through inhalation. He remarks: "I have been pleased with the operation of this ether; it is diffusible in its action like the other ethers, it possesses the peculiar properties of chlorin, and it has this advantage over the sulphuric or other ethers, that it is always grateful. I have known no child refuse it." In the light of the current prohibition movement it is interesting to read a further comment of the editor, Professor Silliman: "We ought to discountenance any other than a medical use of this singular solution; unless indeed it should be found of utility in some of the arts. He would be no benefactor of his species, who should add a new attraction to intoxicating spirit."

The second item of historical value relates to the earliest analyses of human gastric juice obtained by Dr. William Beaumont from his classic case of gastric fistula. In his entertaining life of Beaumont, Jesse S. Myer has recorded how samples of the secretion were submitted to Professor Silliman at Yale. The latter, desiring the support of a chemist of wider experience in organic analysis, sent a sample to the far-famed Berzelius of Sweden. The reply of the latter, published in *Silliman's Journal*,[3] affords an interesting commentary on the status of physiologic chemistry in the early decades of the nineteenth century. The gastric juice sent in April, 1833, did not arrive at Stockholm until the close of the month of August; yet Berzelius reports that "it had not become at all putrescent." This is in accord with the observation of Spallanzani, who reported many years before that the gastric juice is antiseptic.

The unique character of the hitherto unanalyzed gastric fluid proved a stumbling block even to Berzelius' skill as an analyst. Here is his comment: "I could not make this analysis with any hope of success. I assure you that I commenced, but the difficulties immediately arrested me. On testing the gastric juice with litmus paper, I found it strongly acid. The acids are for the most part volatile. . . . Now it was necessary to make a plan of the analysis—but how could I make a plan, the nature of the substances to be separated being unknown?" Thus it was left to Prout to discover the true nature of the acid secreted by the stomach.

Current Comment

THE TREATMENT OF INSANE SOLDIERS

Under the heading of "A Crying Outrage,"[1] the *North American Review's War Weekly* editorially protests against the treatment of soldiers suffering from shell shock, who, the reader is informed, are sent to St. Elizabeth's, the government hospital for the insane. "The mere fact," says the editorial, "that men suffering from shell shock should be confined in an institution where conditions must inevitably aggravate their malady, makes it imperative that the attention of the public be called to such heartless and unscientific treatment." These ideas of insanity are evidently quite as accurate as the writer's knowledge of the plans being followed by the Surgeon-General of the Army in caring for the class of cases referred to. Many of the men committed to the insane asylum, according to the *War Weekly*, "are keenly alive to the danger involved," "they plead pitifully to be sent elsewhere," "they argue with force and lucidity that the character of their affliction is only temporary," they insist that "incarceration in an insane asylum, where they are thrown with the hopelessly insane, must almost inevitably aggravate their troubles, and probably will change what are now temporary aberrations into permanent insanity." This description of nervous diseases is interesting, though hardly authoritative, and impresses no one except the uninformed reader. The medical profession and the American public have consistently and unhesitatingly supported the administration of the Medical Department of the Army. They have as yet had no cause to regret their confidence. While they will hardly regard the editor of the *North American Review* as a competent or qualified critic on medical subjects, it is perhaps not amiss to state the facts regarding the treatment of soldiers suffering from nervous and mental conditions developing in the service. The so-called shell shock cases are not sent to St. Elizabeth's; only general paretic and unimprovable insane epileptics are sent to that institution from the Army; all other insane patients are treated in military hospitals until the possibility of recovery or improvement is eliminated. Special hospitals for mental cases have been established at Fort Porter, N. Y., Danville, N. Y., and East Norfolk, Mass. Special beds for mental patients have been set aside at Bloomingdale Hospital, New York. Special wards for these patients have been created at Walter Reed Hospital, Fort McPherson, Fort Sheridan, Fort Benjamin Harrison, Letterman General Hospital, Fort Sam Houston and Madison Barracks. These special hospitals and wards have been purposely distributed over the country so that patients may be treated as near their homes as possible. They are in charge of psychiatrists and specialists of experience, drawn, for the most part, from the civil hospital services. Patients recovering within four months are discharged from the service; those showing *no improvement* at the end of four months' treatment are transferred to St. Elizabeth's in accordance with Army regulations. Before being so transferred, they are discharged from the service, as St. Elizabeth's is a government hospital under the care of the Department of the Interior and is not in charge of the Medical Department of the Army. Shell shock does not mean insanity, and the patients suffering from shell shock alone never see St. Elizabeth's. In caring for the health of our army of more than 4,000,000 soldiers, the Medical Department has established an enviable record. It is not even presumable that such treatment as that described in the editorial referred to occurred, or that it could occur. In any event, how much better would it have been if, instead of making such an attack as this, the *Weekly* had simply asked for the facts before commenting. If any suspicion exists as to the treatment of ill or wounded soldiers or sailors, in any instance, the Surgeon-General of the Army, or Navy, will undoubtedly be very ready to give the facts regarding any such instance, or an opportunity for an investigation.

A LINE OFFICER'S OPINION OF THE ARMY MEDICAL DEPARTMENT

Hon. F. H. La Guardia, member of Congress from New York City, has recently returned to his place in the House of Representatives after serving with the American Expeditionary Forces in France as a major of the line. In a recent debate in Congress, Mr. La Guardia took the opportunity to reply to the criticism that had been made two days before regarding Walter Reed Hospital. The criticism was contained in a letter to a member of Congress regarding the treatment given an officer who had died in the contagious ward of the hospital. On referring the letter to the Surgeon-General, an immediate investigation was directed and one of the leading internists on duty at the Surgeon-General's Office was detailed to make the investigation. The report disclosed that the officer in question was admitted to the hospital on the sixth day of a pneumonia following influenza; at the time of admission, the patient's temperature was 104; pulse, 100; respiration, 32; the patient was cyanotic with definite consolidation, dulness, bronchial breathing and moist râles—in a word, he presented the typical picture of an advanced pneumonia. He died in twenty-four hours. A carefully detailed report submitted to the Surgeon-General revealed that the medical attention given the patient was of the highest character and that there was no evidence of neglect in any way. In asking to have the report to the Surgeon-General introduced into the record, Major La Guardia took occasion to pay a high tribute to the work of the Medical Department abroad. Coming from a distinguished Army officer and a medical layman who has seen the workings of the Medical Department of the Army at first hand under conditions as they exist at the front, Major La Guardia's impressions are of the highest value. He said:

> Mr. Chairman, it has been, and I suppose it will be so often, my unpleasant and painful duty to criticize various departments and bureaus of our government for their conduct of the war, that it is a pleasure on this occasion to testify to the excellent work and the perfect organization of the Surgeon-General's Office overseas. The gentleman from New York (Mr. Haskell) had read the other day a complaint about a case in the Walter Reed Hospital, in Washington. I have no actual information as to this particular hospital or what the Surgeon-General's Office has been doing in this country during the war, so I asked for a report covering that particular case. I will have the clerk read the report, which is a full and complete answer to the complaint read into the record the other day. It is but fair to have it before the members and the country, inasmuch as the other side of the question was presented to the House.
>
> I want to say that our base hospitals overseas were perfect. The work performed by the medical department right near the firing lines was wonderful. The work of our medical corps overseas was a revelation and a lesson to the armies of our allies. It is the one branch that could teach and did not require to learn from others. The sanitary work in our camps kept the disease down to an unprecedented low percentage. The best medical men of the country responded to the call, and fortunately each man was put, as far as practicable, to work for which he had specialized. The medical department of our service overseas came out of this war with a 100 per cent. perfect record.

ANTIVIVISECTIONISTS ATTACK THE RED CROSS

The *Open Door* and the *Journal of Zoophily*, antivivisection journals, recently published "A Call to Arms." This is signed by Mrs. Diana Belais, editor of the *Open Door*. This "manifesto" amounts to a rabid attack on the Red Cross, and was published at about the time the recent Red Cross drive was starting. The attack opens with this appeal: "Please remember the tyrannical methods frequently used by the Red Cross and be prepared to resist them." It closes with the adjuration: "Do not let us weaken our own cause by assisting in placing on our necks indefinitely an incubus like that of the Red Cross." The readers are told that they must fight for "freedom from coercion at the hands of health boards and their medical-political henchmen." What is meant by this "freedom" is indicated by a standing invitation signed by Mrs. Diana Belais on the last page of the cover of the *Open Door*. It is addressed to "all Anti-Vaccinationists, Anti-Vivisectionists, Eclectics, Homeopaths, Chiropaths, Osteopaths, Naturopaths of all branches, Christian Scientists, New Thoughtists, Theosophists, Medical Freedomists . . . to enroll as active participants in an Association of Free People against Medical Tyranny." Certainly the appeal is made in a catholic spirit, at least so far as regards those who are to be included. There may be some "paths" or "ists" omitted, but even those mentioned ought to form a very happy (?) combination. We commiserate our homeopathic and eclectic friends, who undoubtedly have been included without their consent. The attack on the Red Cross—an organization which has done marvelous service for our soldiers at home and abroad—is, if those who make it did but realize, a piece of crass stupidity which cannot fail to create antagonism to the misguided editor of the *Open Door* and her deluded friends. The Red Cross is too deeply rooted in the love and admiration of all people to be disturbed by such nonsense. In their aspirations for notoriety, the rabid antivivisectionists never seem to hesitate to attack the most philanthropic organization, the most altruistic individual, and even the liberal government which permits them to speak their bigoted utterances without restraint.

THE REWARD OF FASTING

Some of our readers, if there are any whose memory carries them back more than a generation, will recall the popular interest awakened by the demonstrations of the person termed the Great Faster. This individual, Dr. Harry Tanner, who in the eighties of the last century declared that he would live longer than other men by fasting while they ate, drank and were merry, has just died at the age of 91 years. During visits to England in the days of his enthusiasm he actually gave "lessons" on how to fast; and his bold utterances provoked some discussion on the part of both the laity and the profession. The theories that have been advanced to account for exceptional old age are so varied and contradictory that it would be rash indeed to utter a parting "Well done" to the departed faster. The liberal use of tobacco and spirits, as well as the most rigid abstemiousness, have equally been credited with age-prolonging virtues. What the liberal ingestion of sour milk is reputed to have accomplished for some persons in stretching their span of life might equally well be charged to sour grapes in the case of others. And as for the virtues of fasting, they seem to find ever new applications. For one person they form the basis for earnest religious observance; for another they constitute a universal panacea for health; and how far fasting is from being out of fashion is indicated by its popularity at the present moment as a mode of treatment in diabetes. From some of the reports it would seem as if the rationing system of the Germans and their allies, the Turks, had vacillated between rigid economy in nutrition and actual starvation—presumably to the advantage of those who survived. The press notices of the demise of Dr. Tanner leave us somewhat in doubt as to whether the reward of fasting was worth the effort; for the message regarding this "foodless man" contained the laconic sentence: "He is believed to have ended his days without relations."

UNSUCCESSFUL ATTEMPTS TO TRANSMIT INFLUENZA EXPERIMENTALLY

Two extensive attempts have been made under the auspices of the United States Public Health Service and the United States Navy—one at Boston and one at San Francisco—to transmit influenza experimentally.[1] Sixty-eight men from the naval detention camp at Deer Island volunteered for the experiment at Boston. These volunteers had been exposed in some degree to influenza, but most of them gave no history of any illness suggestive of an attack of influenza. Inoculations were made of pure cultures of the influenza bacillus, of secretions from the upper air passages of persons in the early stage of influenza, and of blood from typical cases of influenza. Suspensions of freshly isolated bacilli were introduced into the nose. Both filtered and unfiltered secretions from the air passages of typical cases of influenza in the active stages of the disease were inoculated by means of spraying and swabbing of the nose and throat. Volunteers were placed in very close association for a few minutes with each of ten selected influenza patients, who were instructed to cough directly into their faces. Filtered secretions and the blood from influenza patients were injected subcutaneously into a group of volunteers. In San Francisco the volunteers had not been exposed to influenza at all in the present epidemic, but they had been vaccinated with large doses of a mixed vaccine of influenza bacilli, pneumococci and hemolytic streptococci. In view of the negative results, however, of such vaccinations in controlled experiments,[2] it is believed that this vaccine may be regarded as having no influence. Here also suspensions of influenzal bacilli were introduced into the nose. In one group the suspension was first filtered through a Berkefeld candle. Filtered, as well as unfiltered, emulsions of respiratory secretions from active cases of influenza were introduced into the nose. Filtered emulsion was dropped into the eye and injected subcutaneously. Blood taken during the active stages of influenza was injected subcutaneously. Not one of the many volunteers in these two series of experiments developed influenza. Three volunteers who received the filtered secretions developed acute tonsillitis, and in two, cultures gave almost pure growths of hemolytic streptococci. That so many attempts to transmit influenza should fail is a great surprise and disappointment in view of the positive results reported by Nicolle and Le Bailly.[3] The results of these experiments may naturally be the subject of much speculation. However, it is certain that the cause of influenza remains a mystery to be solved only by continued experiment. In the meantime, we must not relax our effort to control the disease and its complications according to the principle that both are droplet infections, with special attention to the probabilities brought out by these experiments that uncomplicated influenza is infectious in the earliest stages of the attack.

Treatment of Enlargement of the Thymus.—A recent abstract in the *Correspondenz-Blatt für Schweizer Aerzte* states that W. Birk insists on the absolutely different clinical picture presented with simple enlargement of the thymus and that with the thymus-lymphatic state. The former, simple enlargement of the thymus, usually develops during fetal existence, and the trachea is compressed by the abnormally large thymus even before birth. Death is the result of suffocation, the already damaged trachea becoming compressed to the point of suffocation. The status thymicolymphaticus, on the other hand, is not congenital, and in this the constitution and the food are of paramount importance, while these have no influence on the congenitally enlarged thymus. But the latter can be modified by the roentgen rays, and Birk reports five cases in which the excessively large thymus promptly shrank to normal size under the exposures. In one case the gland enlarged again later, but in all the others the cure was prompt and permanent.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending January 17, there were in the Medical Corps 626 officers. This personnel includes 48 majors, 87 captains and 491 lieutenants. There were in the regular Medical Corps 24,871, a decrease of 1,146 since the previous week. Discharges to date include 10,579 officers.

Distinguished Service Cross Awards

The Distinguished Service Cross has been awarded to the following medical officers:

Passed Assistant Surgeon FREDERICK R. HOOK, U. S. Navy, attached to 5th Regiment United States Marine Corps. "For extraordinary heroism in action near St. Etienne, France, Oct. 4 to 6, 1918. Passed Assistant Surgeon Hook established an advanced dressing station in an exposed position under heavy artillery and machine gun fire. He worked fearlessly and unceasingly giving first aid to the wounded and directing their evacuation until ordered to move to the rear."

First Lieut. JOHN F. WEBER, M. C., U. S. Army, Florence, N. J., assigned 311th Infantry, "For extraordinary heroism in action near Vieville-en-Haye, France, Sept. 29, 1918, Chevieres, France, Oct. 15, 1918, and Grandpre, France, Oct. 25, 1918. On September 29, and the following days, Lieutenant Weber, returned to his aid station under shell and machine gun fire giving medical aid and directing the evacuation of wounded. On October 15 he established an unprotected aid station and was slightly gassed; he continued to give first aid to the wounded and directed their evacuation. On October 25, Lieut. Weber left his battalion in support and continued to the town of Grandpre where he established an aid station, keeping on his work through heavy bombardment of the town."

Lieut. OTHEL J. GEE, M. C., U. S. Army, 20th Field Artillery. "For extraordinary heroism in action near Vieville-en-Haye, France, Sept. 27, 1918. Lieutenant Gee voluntarily ran to the assistance of a wounded soldier, dressed his wounds, and carried him to shelter through severe shell fire."

Passed Asst. Surg. PRESTON ALEXANDER McLENDON, U. S. Navy, attached 5th Regiment, U. S. M. C. "For extraordinary heroism in action near Blancmont, France, Oct. 3 and 4, 1918. During heavy action, Passed Assistant Surgeon McLendon, continually pushed his dressing station to more advantageous positions. Although in great danger because of a severe shelling, Surgeon McLendon dressed his patients in an exposed position, using his dugout for the seriously wounded."

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L., signifies lieutenant; C., captain; M., major; L.C., lieutenant-colonel, and Col., colonel.

ALABAMA

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending January 17, there were in the Medical Corps 626 officers. This personnel includes 48 majors, 87 captains and 491 lieutenants. There were in the regular Medical Corps 24,871, a decrease of 1,146 since the previous week. Discharges to date include 10,579 officers.

Distinguished Service Cross Awards

The Distinguished Service Cross has been awarded to the following medical officers:

Passed Assistant Surgeon FREDERICK R. HOOK, U. S. Navy, attached to 5th Regiment United States Marine Corps. "For extraordinary heroism in action near St. Etienne, France, Oct. 4 to 6, 1918. Passed Assistant Surgeon Hook established an advanced dressing station in an exposed position under heavy artillery and machine gun fire. He worked fearlessly and unceasingly giving first aid to the wounded and directing their evacuation until ordered to move to the rear."

First Lieut. JOHN F. WEBER, M. C., U. S. Army, Florence, N. J., assigned 311th Infantry, "For extraordinary heroism in action near Vieville-en-Haye, France, Sept. 29, 1918, Chevieres, France, Oct. 15, 1918, and Grandpre, France, Oct. 25, 1918. On September 29, and the following days, Lieutenant Weber, returned to his aid station under shell and machine gun fire giving medical aid and directing the evacuation of wounded. On October 15 he established an unprotected aid station and was slightly gassed; he continued to give first aid to the wounded and directed their evacuation. On October 25, Lieut. Weber left his battalion in support and continued to the town of Grandpre where he established an aid station, keeping on his work through heavy bombardment of the town."

Lieut. OTHEL J. GEE, M. C., U. S. Army, 20th Field Artillery. "For extraordinary heroism in action near Vieville-en-Haye, France, Sept. 27, 1918. Lieutenant Gee voluntarily ran to the assistance of a wounded soldier, dressed his wounds, and carried him to shelter through severe shell fire."

Passed Asst. Surg. PRESTON ALEXANDER McLENDON, U. S. Navy, attached 5th Regiment, U. S. M. C. "For extraordinary heroism in action near Blancmont, France, Oct. 3 and 4, 1918. During heavy action, Passed Assistant Surgeon McLendon, continually pushed his dressing station to more advantageous positions. Although in great danger because of a severe shelling, Surgeon McLendon dressed his patients in an exposed position, using his dugout for the seriously wounded."

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L., signifies lieutenant; C., captain; M., major; L.C., lieutenant-colonel, and Col., colonel.
